Reliability can refer to several different types of estimates of consistency. Alternative form reliability refers to the degree of consistency between two equivalent forms of a measure. Split-half reliability refers to the consistency between two randomly-created sections of a single test. The internal consistency statistics coefficient $\alpha$ (also referred to as Cronbach's $\alpha$) and the related Kuder-Richardson 20 (or “KR-20”) can be thought of as the mean of all possible split-half estimates. Test-retest reliability refers to the consistency of scores on separate administrations of the same test. Determining an appropriate delay between the initial and follow-up administrations can be difficult. As examples, if the chosen delay is too long, expected changes (e.g., learning) in the respondents may contribute to a low test-retest correlation, which may be mistaken for evidence of invalidity. If the delay is too short respondents’ remembering and repeating their responses from the first test may contribute to a high test-retest correlation, which may be mistaken as evidence of validity. Ideally in this context, respondents would receive the exact same score on the test and the retest. If scores tend to go up or down from the test to the retest, the correlation between the test and the retest will be reduced unless all scores rise or fall by the same amount.

Inter-rater reliability refers to the extent to which judges or raters agree with one another. As an example, assume two judges rate teachers on the extent to which they promote a mastery orientation among students. The reliability of the judges can be estimated by correlating the scores of both judges. A 1965 study by John E. Overall found that the effective reliability of the judging process (i.e., of both judges together) can also be estimated; effective reliability will generally be better than the reliability of either judge in isolation. One problem in estimating inter-rater reliability is that the judges’ scores may reflect both random error and systematic differences in responding. This problem reflects a fundamental concern about the representativeness of judges, and, according to Richard J. Shavelson and Noreen M. Webb in their 1991 publication Generalizability Theory: A Primer, it is addressed in an extension of classical test theory known as generalizability theory.

SAMPLE AND CONTEXT DEPENDENT
The assertion “this measure is reliable” reflects a common misunderstanding about the nature of reliability. Reliability is a property of scores, not of measures, and it is therefore sample and context dependent. A test yielding good reliability estimates with one sample might yield poor reliability estimates with a sample from a different population, or even with the same sample under different testing conditions. The decision about whether to adopt an existing measure should therefore be based on more than a simple examination of score reliability in a few studies. Further, score reliability should be examined on each administration regardless of the measure’s empirical history (Thompson, 2002).

RELIABILITY AND VALIDITY
Reliability and validity are not necessarily related. Validity concerns the extent to which a measure actually measures what it is supposed to. While reliability does set a maximum limit on the correlation that can be observed between two measures, it is possible for scores to be perfectly reliable on a measure that has no validity or for scores to have no reliability on a measure that is perfectly valid. As an example of the latter, suppose that students in a pharmacology class are given a test of content knowledge at the beginning of the semester and at the end of the semester. Assume that on the pretest the students know nothing and therefore respond randomly, while on the post-test they all receive As. Estimating reliability via the split-half method or coefficient $\alpha$ on the pre-test would suggest very little consistency, as would the test-retest method. The test itself, however, would seem to be measuring content taught during the course (indicating good validity).

RELIGION

Though difficult to define from an intercultural perspective, religion informs the lives of virtually every society as a complex system involving beliefs, behavior, organizational structures, and symbols. Problems in satisfactorily defining the term emerge from the manifold ways in which religion expresses itself, the varied roles that it performs both for individuals and for social groups, and the plethora of academic disciplines that study it.

DEFINITION AND SCOPE

Beliefs that may be deemed “religious” range from precisely articulated perceptions of a complex array of anthropomorphic deities, such as the myriad levels of divinity recognized in Hinduism, to vague notions of impersonal, overarching power—for example, the concept of mana recognized in many Polynesian societies. Behaviors include a variety of practices, such as the silent meditation practiced on a personal level by mystics from a diversity of religious traditions, including Buddhism and Christianity, and complicated ritual scenarios involving scores of people such as the annual Sun Dance that has provided the central corporate religious experience for many American Indian groups on the Great Plains. Religion’s organizational structure may be simple groupings of individuals brought together temporarily for specific religious purposes, such as the big meetings held by some Aborigines in the Western Australian desert, as well as multileveled hierarchies that have endured over millennia (for instance, the Roman Catholic Church). Symbolic representations with religious dimensions can be discrete metaphors that stand for a single concept (e.g., a shaman’s characterization of his or her mystical experience as a death and rebirth) as well as variegated iconographic vocabularies of interrelated images, such as that which characterized medieval and Renaissance Christianity and which continues to afford ways for Christians to communicate about their faith.

Social scientists and others have noted that religion plays varied roles in society, including validating other features of a society, such as its political or economic system, and compensating individuals for the limitations that their humanity imposes on them and for the prohibitions dictated by specific societal norms. Religion also has an integrative function as it provides a focus for cultural identity, endorses those values and norms that ensure that a person will truly be a respectable member of the society, and discourages behavior that undermines social cohesion. Religion also offers answers to some of life’s persistent problems, especially the meaning of death and the possibility of an afterlife.

The study of religion is genuinely multidisciplinary, and different fields stress different emphases in their approaches to the concept. Sociologists, for example, usually highlight the organizational structures and patterns of behavior as central to their concerns, whereas practitioners of philosophy, theology, and comparative religious studies focus their attention on beliefs. Literature and art history are most likely to foreground religious symbolism. Priding itself on its holistic approach to society and culture, anthropology is more apt than other disciplines to pay more or less equal attention to all four components of religion.

The problem of defining religion is further complicated when one attempts to differentiate it from other systems of belief, behavior, organization, and symbolism. These attempts often rely on terms that themselves need definition and clarification: sacred, transcendent, supernatural, spiritual, and ultimate. Most of these terms suggest that religion focuses on nonroutine phenomena that are set apart in some way from nonreligious experience (the secular or the profane). But exactly what sets them apart and the degree to which they differ from the rest of life have not been consistently articulated. What may be perceived as sacred phenomena in some systems of belief may be regarded as secular elsewhere. Mysterious lights, for example, may signal the presence of a supernatural entity, or they may be explained as the product of gases emitted by decaying vegetation. One may base the decision whether to eat meat on religious proscriptions, or the decision may be simply a nutritional issue.

Another contributor to the difficulty in defining religion is that although religion is apparently universal—that is, found in all societies—the concept of a system of beliefs, behavior, organizational structures, and symbolism distinct from other social systems is largely a Western construct. Many languages have no equivalent for the English word religion, though the societies that speak those languages evince much that would be considered religious in Western terms.

RESEARCH CONCERNS

Theoretical and methodological approaches to the study of religion generally reflect different emphases in how the concept is defined. Whereas social scientists, for example, usually focus on how religion operates within specific cultural contexts, theologians and comparative religion scholars may examine the nuances of religious beliefs. But one area of concern that has transcended a range of academic disciplines is the issue of origins. For example, a historian may be interested in how Mormonism emerged from the ferment of religious enthusiasm that characterized the burned-over district of western New York in the early nineteenth century, or in tracing the origins of Christian apocalypticism of the twenty-first century to
Zoroastrian beliefs in Persia from perhaps as early as the tenth century BCE.

More fundamentally, interest in origins has often addressed how religion as a system originated in the human individual and collective psyche: as a response to dream experiences (the view of the nineteenth-century anthropologist E. B. Tylor), out of fear and guilt regarding a primordial father figure (one of the ideas articulated by Sigmund Freud), as a product of the human tendency to personify incomprehensible natural forces (articulated by the eighteenth-century philosopher and historian Giambattista Vico, among others), as a method for suppressing social discontent and for promoting adherence to a society’s power structure (advocated by philosophers from Plato to Marx), and even as the product of revelation from a god or other spiritual being or force (the stance assumed by many religious adherents—at least in regard to their own religions). Of course, many other explanations of religion’s origin have been and continue to be proposed, and many of them lack the criterion of testability upon which many academic fields insist in order for an idea to be more than hypothesis. Consequently, many other issues in religion have received more scholarly attention.

Many sociologists, in particular, look to the pioneering concepts of Émile Durkheim, a late-nineteenth-century social scientist who argued that religion is principally a social phenomenon. Drawing upon data from the religions of Australian Aboriginal groups, he proposed that the object of religious belief and behavior was, in fact, the society itself, and that religion operated to maintain social stability through the devotion of its adherents. Whereas many of his contemporaries were more attracted by the issue of religion’s origins, Durkheim concentrated on how religion operated. This concern anticipated the functional emphases of anthropologists Bronislaw Malinowski and A. R. Radcliffe-Brown, who early in the twentieth century examined how religion operated as a support for other social institutions and—in Malinowski’s case—how it might assist believers in their everyday lives by providing ways of dealing with issues that lay beyond their scientific knowledge. Malinowski studied the culture of the Trobriand Islanders, Melanesians who inhabited an archipelago to the east of New Guinea and who relied on seafaring for much of their livelihoods. He noted that Trobriand sailors did not evoke religion when they were operating within the peaceful lagoons just offshore from their island homes, but when they faced the potentially uncontrollable forces of the open seas, they turned to religious beliefs and behavior to complement their knowledge of ocean currents, the weather, and other variables.

Though they might reject the designation “functionalist” as too simplistic for how they approach the study of religion, many social scientists nevertheless continue to deal principally with how religion operates in social life collectively and in the lives of individuals. Durkheim’s belief that the object of religious interest symbolizes the society finds echoes in the more recent ideas about civil religion. Sociologist Robert Bellah has suggested that in many societies—the United States, in particular—patriotism has developed beliefs, behaviors, organizational structures, and symbolism tantamount to a religious system (1967).

Many social scientists have been especially interested in the nature of religious participation: who finds given religious systems amenable to meeting their particular needs and who performs what roles in religious behavior and organization. In heterogeneous, stratified societies such as those in the West, research has attempted to correlate membership in a particular class or caste with participation in a particular religious system or subset thereof. For instance, the wealthy and highly educated populations in the United States are more likely to affiliate with branches of Christianity that stress the importance of formal liturgy, whereas middle- and lower-class individuals prefer Christian groups that stress less organization and underscore instead the importance of personal religious experience. Ethnicity also has been a frequently identified variable in determining religious affiliation. In fact, some ethnic groups in the United Kingdom and France use religion, particularly Islam, to reinforce and signal their ethnic cultural identity. In the latter half of the twentieth century, researchers became more and more interested in ways in which gender might affect not so much a person’s specific affiliation but the nature of that person’s involvement in religion. While the women’s movement was encouraging a more visible, active role for women in many Christian denominations in the West, researchers looking at religions in other parts of the world often found that women traditionally had been central in local religious belief and polity.

Another focus of social scientific interest in religion has been the way in which it interacts with other systems of ideology in a society. Max Weber is an important early figure in this interest because of his demonstration of the way in which Protestant Christianity, especially Calvinism in western Europe, created a milieu conducive to the emergence of capitalism by emphasizing individualism and hard work, among other values. Of particular interest in the late-twentieth and twenty-first centuries has been the association between religion and nationalism. Islamic-based governments, primarily in the Middle East, have become among the most important participants in global politics, and competition between different branches of Islam (Suni and Shia, in particular) has characterized their internal politics. Christianity has assumed a similar role in some Western nation-states such as the United States, where fundamentalist groups have become powerful elements on the political landscape. Sociologists and
political scientists have shown particular interest in measuring the ways in which religious affiliation has affected the voting patterns of the U.S. electorate and in shaping the programs of the politicians they support.

An important and very fundamental development in social scientific interest in religion concerns the way in which scholars position themselves in regard to their subject. Conventionally, social scientists have been urged to develop a stance of methodological agnosticism in which they eschew their own religious beliefs at least temporarily and adopt a perspective of cultural relativism that is not concerned with whether a religious belief is true or whether a ritual actually produces the results that its practitioners desire. Instead, researchers have attended to the internal consistency of belief systems, the social and cultural functions of ritual, and the extent to which adherents lend credence to beliefs and rituals. Recently, however, some social scientists have begun to recognize that this perspective brings with it certain assumptions that color what researchers observe, how they report what they encounter, and the directions taken by their analyses. Influenced by the set of ideas loosely known as “postmodernism,” researchers have become more aware of the role of their own religious ideas in their work and have become more forthcoming about those ideas. The cultural anthropologist Victor Turner, for example, was usually very open about his own Roman Catholicism in his work focusing on the symbolic dimension of religious systems. In addition to this move toward reflexivity on the part of religious researchers, some social scientists have begun to accept that religious beliefs may often stem from actual wondrous events that an individual has experienced and which the social group interprets in terms of the events’ relation to indigenous ideas about the sacred, the supernatural, the spiritual, or the ultimate.

New tools have allowed social scientists to explore traditional areas of religious study more fully and accurately. The availability of computer programs, for instance, allows demographic studies to be done more quickly and with a larger number of variables than was feasible before the computer age. Meanwhile, technology has taken religious studies into some new, still controversial, and largely unexplored areas such as the possibility of a genetic basis for the need for religion. Interestingly—and perhaps counterintuitively—the growth of technology during the latter half of the twentieth century did not parallel a decline in religious adherence; instead, many religions have witnessed significant growth as technology has blossomed.

DEMOCRGRAPHICS
Literally thousands of religious systems flourish throughout today’s world. Although many of these appeal only to small groups (and have consequently been labeled “tribal” or “primal-indigenous” religions), even these may exert international influence through the globalized mass media and through such phenomena as cultural tourism. Other religious systems are truly world religions whose practitioners believe that they can and should promulgate their beliefs to everyone. Despite their purported international scope, though, these world religions are often focused on specific territories. For example, the largest religious system, Christianity (with more than two billion adherents), developed in the eastern basin of the Mediterranean Sea and then spread primarily through Europe and then to those parts of the world that were subjects of European colonialism. Most branches of Christianity retain primary geographical ties with Europe or with the United States, but some are flourishing most luxuriantly in other parts of the world—Roman Catholicism in Central and South America and in Africa, for example.

Meanwhile, Islam—second in number of adherents to Christianity with perhaps a billion and a half followers—maintains its primary geographical association with southwestern Asia and southeastern Europe. But it has spread throughout the world, and, in fact, the country with the most Muslims is Indonesia. Hinduism, with close to a billion practitioners, remains principally associated with the Indian subcontinent, and Buddhism, with maybe half a billion adherents, also has an Asian focus. Nevertheless, both these religions have had enormous influence elsewhere, especially as replacements for or supplements to Christianity. The diaspora of the Jewish population has made Judaism a world religion with a symbolic attachment to the nation of Israel.

As contact between societies becomes more efficient, these world religions as well as more local systems of belief, behavior, organizational structures, and symbolism will spread more widely. Meanwhile, they will continue to influence one another to create syncretistic systems such as the Native American Church, which blends Christianity, various North American Indian religions, and ritual behavior that apparently originated in Mexico; and Vodoun, the principal religion of Haiti, which merges Roman Catholic Christianity and several West African religious systems, with influences from native Caribbean religions. The endurance of religions whose roots lie in the distant past, as well as the emergence of new religions, often the result of syncretism and other processes of cultural exchange, ensures that social scientists and other scholars who specialize in the study of religion will not lack for subject matter any time soon.

Religiosity is a term used by social scientists to refer to religious behavior. Social scientists generally view religion as a cultural system of shared beliefs and rituals that offers a sense of transcendent meaning and purpose. Religion is often constrained within the natural and material categories. Religiosity therefore refers to the way people and communities are influenced by religious ideas and shape social reality accordingly.

From its inception, religiosity has been a central issue for social scientists. The German political philosopher Karl Marx viewed religion as an ideology of capitalist oppression. For Marx, religion compensated for the needs denied under capitalism, and the elimination of religion was indispensable to human emancipation. The German sociologist Max Weber (1864–1920) viewed religion as a meaning-making system that determined human behavior and shaped societies. Weber predicted that with the increase of rationalization there would be a “disenchantment of the world” that would lead to the decline of religious beliefs. The French sociologist Émile Durkheim viewed religion as the very essence of society that constrained individuals from egocentric behavior while simultaneously enabling them to adjust and function in social settings.

In the 1950s and the 1960s social scholars, most notably Peter L. Berger, proposed the secularization theory. The secularization theory claims that modernization necessarily leads to the decline of religion, both in society and in the minds of individuals. This in turn leads to the privatization of religion that marginalizes religion from the public sphere. Therefore as modernity ushered in plurality, subjectivity, and different authorities for legitimation, religion, unable to deal with these challenges, eventually withdrew from the public realm. According to the theory, the future of religion is a private one, eventually existing mainly in the private lives of individuals.

Decades after the secularization theory was popularized, Berger and its other champions revised and reconsidered the theory in light of an un secularized modern world. Modernity not only did not secularize society but it created a counter- secularization movement that resulted in the increasing influence of religiosity in the modern world. In Public Religions in the Modern World (1994) Jose Casanova argued against the assumption that the increasing differentiation between religious and public institutions automatically leads to the decline of religion. Casanova claimed that public religions do not necessarily challenge the foundation of modern liberal society. In fact Casanova suggested that public religions can help advance modern agendas such as those of human rights and democracy.

Fundamentalism

One public form of religiosity is the religious phenomenon known as fundamentalism. Fundamentalism is characterized by a strict adherence to religious doctrines in their original form in order to restore a previous social order in the present world. The sociologist James Davison Hunter argued that fundamentalism is a direct product of modernity. Hunter characterized fundamentalists as those who believe that something has gone wrong in human history. Religious fundamentalists believe that their sacred order for human life has been disturbed and they must correct it to the best of their abilities. Hence religious fundamentalists are religious adherents who believe that they must restore the sacred order that their deity intended for this world. Though the term fundamentalist is ambiguously used to characterize both peaceful devout Muslims and...
and extremist terrorists, it is important to note that religious fundamentalism does not always involve acts of violence. As the scholar Nancy T. Ammerman noted, one characteristic of many fundamentalist sects is that they are separatists. They seek to restore what they believe to be a sacred order only for their religious community. Many of these fundamentalists retreat from the secular world in order to construct the social reality of their liking. For example, the fastest growing Christian denominations in the United States are religious groups with fundamentalist beliefs.

One of the most notable branches of Christian fundamentalism is Pentecostalism. This form of Christianity emphasizes the experience of the Holy Spirit. Adherents are highly expressive and emotional, and their religious rituals often involve spiritual healings and the act of speaking in tongues, which is the utterance of what appears to be an unknown foreign language or simply nonsense syllables. In less than one hundred years Pentecostalism, along with its offshoot the charismatic movement, has become the largest segment of Protestant Christianity and the second largest Christian tradition after the Roman Catholic Church. In the early twenty-first century one out of every four Christians in the world is Pentecostal or charismatic. Pentecostal Christians use mass media to carry their message around the world and are arguably the most visible form of Christianity in the world.

The resurgence of religiosity in social sciences is especially clear at the beginning of the twenty-first century. The clear relationship between church and state in the United States was apparent to the great French observer Alexis de Tocqueville in the 1830s when he noted that churches and other voluntary organizations were the cradle of American democracy. The interconnectedness of religion and politics should not be confused with the conflict between church and state, though the clash of both are increasing in modern times. The conflict between church and state is institutional, while the conflict of religiosity and politics is within individuals. All religious citizens must negotiate between personal sacred beliefs and secular laws designed to appease a plurality of religions. This creates a cognitive dissonance that often leads to public confrontations between religion and politics. In The Clash of Civilizations and the Remaking of World Order (1997) Samuel Huntington traced the shifting focus of global conflict toward the end of the twentieth century. He noted that international conflict has shifted from ideological differences to religious and cultural conflict. Gone are the days when the United States allied with Islamic fundamentalists to repel the then communist Soviet Union out of Afghanistan. Under Huntington's new order, religiosity determines enemies and allies.

RENT
The term rent has two meanings in economics and one taken from everyday usage. When a person leases an apartment or house from its owner, the lease provides for a payment to the owner. Although commonly called rent, it is very different in both orientation and calculation from the two uses in economics, namely, economic (or Ricardian) rent and rent-seeking, which are themselves very different from each other.

ECONOMIC RENT
The rent paid to an owner of leased property is a composite payment. It covers or includes the following items: the cost of the land, the cost of improvements, interest on the combined costs, the amount of appreciation of the land and improvement values, taxes, the cost of any services provided along with the leased property, and, given the overall workings of demand and supply, any further profit; all of which are calculated on a per-period basis. Should the owner have a mortgage, the owner's receipt of rent enables the owner to accumulate equity in the prop-
Rent

should the renter arrange with the present owner to purchase the property, it is the former renter, now owner, who accumulates equity in the property by paying off the mortgage, if any. The principal connection with economics, or economic theory, of such rent is that the rent paid for the leasing of the property must be worth its expenditure to the renter (including consideration of alternative leasing) and must be suitable, relative to the owner’s costs and alternative leasing), to warrant for both of them to enter into the rental contract, or lease.

The concept of economic rent stems from the English economists David Ricardo and Thomas Robert Malthus in the early nineteenth century. Ricardian, or economic, rent is the return to the owner of land (or any factor of production) that is fixed in supply and whose level is governed by the pressure of population growth. With trivial exceptions, such as filling in shallow bodies of water for one reason or another, the amount of land does not change with a change in the demand for it. The demand for land is driven by the need for land on which to grow crops and to erect homes. This need increases with population increase and is due solely to the growth of society. The increment in the price of land thus generated is widely considered unearned compared to situations in which investment in improving land and its appurtenances takes place.

Several additional features stemmed from early-nineteenth-century study. One feature is that land rent is differential with regard to location and to fertility, Increments or decrements of property value will reflect relative location and fertility, and likely will not be constant in either amount or percentage change. The second feature is a specific form of the first, namely, that as increasing levels of labor and capital are applied to the same amount of land, output per unit of input will fall. This is called diminishing returns. The third feature is due to the fact that not all land is equally fertile or located equidistant to a given point. This means that as the price of food increases due to the population-driven demand for food and thereby land, the increments of price (rent) of the more fertile or better situated land will increase more rapidly than those of less fertile or worse situated land. The fourth feature is that rent is a residual category such that any tax on land rent will have no disincentive effect on the level of food production on the land.

Given both that the increased price of pure, unimproved land is due to the growth of society and that any tax on the rent will have no adverse effects on income-maximizing owner calculations and farming, it has followed for many economists that a tax on unimproved land would have no negative effects and would be a fit subject of taxation. Objection to this reasoning arose from those who felt that acquisition of the increased value was one of the rights of property. The rejoinder to that objection was this: Land-value increments being due to the growth of society and not the activities of the owner, not taxing land rent but maintaining the same governmental budget, meant that tax revenues would have to come from taxes levied on productive activities. Nevertheless, a tax on land-value increments conflicted with the principle of conservatism, that appropriation of the increase of value was a right of property. However, for the American economist Henry George (1839–1897), for example, whose reasoning was initially based on Ricardo’s, nothing was more conservative than promoting income in accordance with productivity rather than unearned increments.

The theory of Ricardian rent must be supplemented by consideration of the competition over pieces of land by people who had different, and conflicting, uses for the land. The idea of quasi-rent was developed by the English economist Alfred Marshall to identify the return to owners of factors of production, such as one’s own labor or pieces of capital, that are in temporary inelastic supply.

**RENT-SEEKING**

The second notion of rent in economic theory is that of rent-seeking. The idea is that rent is the difference between two sets of rights, that people could invest money in efforts, through lobbying, legislation, and/or litigation, even bribery and extortion, to change the law in their favor, thereby increasing their incomes. Rent-seeking would engender counter-measures by those threatened with loss. The result would be wasted resources deployed in such activities. The objection to rent-seeking theory is that prohibition of such activity, were it actually possible, would remove the opportunity to address grievances, perpetuate the law in existence at the time of prohibition, and deny people their legal and constitutional rights, including their right to a lawyer, and their right to participate in government as well as limit competition. The perpetuation criticism is particularly objectionable, inasmuch as modern urban industrial society and political democracy would never have been feasible had the beneficiaries of the old post-feudal order had a veto, as it were, on legal, political, and social change. Anne Krueger’s more limited model, centering on bribery and extortion, is much less amenable to criticism along these lines than several other broader and less discriminating versions of rent-seeking.

Both theories, Ricardian rent and rent-seeking, are greatly affected by the situation that, under post-feudal structures, land ownership conveyed important rights of governance and therefore control of social evolution.

RENT CONTROL

Rent controls can be broadly defined as governmental regulations that limit landlords’ ability to set and increase rents freely on residential properties. Rent controls often coincide with a host of other regulations concerning landlords’ responsibilities and tenants’ rights in a rental arrangement. Most rent controls are one of two types: rent ceilings, which place hard limits on the amount of money a landlord can charge for a rental unit that is based on the unit itself; and tenancy rent control, which is a set of regulations that limit the actions a landlord can take during the tenure of a sitting tenant, including limitations on landlords’ ability to increase rents.

Rent ceilings (or first-generation rent controls) are the most commonly studied type of rent control, but have become quite uncommon in practice. Most rental ceilings came into being at the end of World War II (1939–1945) to help mitigate expected disruptions in the rental housing market due to the demand shock of veterans returning from overseas service in the war. The most well-known example is in New York City, where a number of rental properties are still controlled under a rent ceiling. Tenancy rent controls (also known as second-generation rent controls) are much more common in the contemporary world. Most tenancy rent control laws were enacted in the wake of the global economic downturn of the mid-1970s that brought high inflation, and many were then abolished in the 1980s and 1990s. Tenancy rent controls are still relatively common in North America and Europe and elsewhere. Tenancy rent controls are typically one component of a host of policies that strengthen tenants’ rights in the rental housing market. In addition to limiting the amount of rent increases a landlord can impose on a sitting tenant, they often regulate or prohibit the practice of collecting nonrefundable deposits, limit the ability of landlords to evict sitting tenants, and restrict the use of fixed-term contracts.

One particular aspect of tenancy rent controls that differs considerably from rent ceilings is the “vacancy decontrol” provision most employ. This provision frees landlords to set rents freely once a rental unit becomes vacant. The common justification for tenancy rent control is the shift to the landlord in the balance of power once a tenant has taken up occupancy in a rental unit due to the expense to the tenant (both financial and emotional) of vacating the unit and moving elsewhere. As arbitrary evictions are generally prohibited, it is necessary to limit the landlords’ ability to increase rents on sitting tenants so that they are not deliberately priced out of the unit to affect the same result as an eviction.

Rent ceilings are fairly straightforward to analyze and have thus secured a place in almost every basic textbook on economics. The artificially low rents created by these laws create excess demand for apartments. This excess demand would normally drive prices up, but the regulation prevents this, leaving a group of potential tenants unable to find housing. Those who do secure housing are better off as they are paying less than they would in the absence of the policy. Landlords receive less than they would in the free market, which serves to limit the supply of apartments. So there are fewer units available under rent control than without, and there are winners and losers among those who want housing at the rent ceiling price: the winners are those that are able to find a rental unit and who pay the depressed rent, and the losers are those that cannot find housing.

Tenancy rent controls are less straightforward to analyze. Since initial rents are generally set to market clearing rates, the problem of excess demand is not realized. However, as rental increases on sitting tenants are limited, it creates a situation where apartments are more valuable for those that are able to remain in them for a long time as they get the benefit of diminishing real rents, and these types will therefore bid up initial rents. Those that are more peripatetic are likely to find initial rents too high as they will not be able to realize the full benefit of decreasing real rents. The result in this situation is a different type of winner and loser. The winners under tenancy rent control are those that can remain in an apartment for a long time (perhaps older, more established individuals) and the losers are those that need to move more frequently (perhaps younger, less established individuals). In the end, landlords are able, through the setting of high initial rents, to do just as well under tenancy rent control as in an unregulated market and therefore supply is not affected.

REPARATIONS

The term reparations refers to a concept and tool for providing monetary payments to members of aggrieved groups based on past wrongful actions against them or their ancestors. Reparations are used for addressing injuries and damages in relations among nations, ethnic groups, and other victims of sustained economic and sociopolitical injustice or military or police aggression. Examples include reparations paid to victims of the German Holocaust in Europe from 1930 to 1945 and Japanese Americans who were partially compensated for their internment and loss of property in the United States during World War II (1939–1945). Earlier reparations were paid by Germany to the Allies after World War I (1914–1918), but in a manner and intensity that probably contributed to reopened hostilities later in the century.

The reparations concept is being thought of by some as a potentially useful tool for helping to resolve chronic ancestral grievances in many situations worldwide, including in Northern Ireland, the Balkans, the Middle East, South Asia, and elsewhere.

In the United States, the idea of reparations has gained strength as a way to remedy injustices against African Americans as a group, as well as Native American Indians and Native Hispanic American Indians. This latter debate over what many call reparations has often been a catchall for discussion of a wider range of concerns in social policy and the expression of other agendas. In that sense, some reparation advocates seek monetary damages for their ancestors’ pain and suffering, for their loss of language and African identity, and for the slave trade itself. The debate has also been characterized by imprecision, and the parties to the argument often mischaracterize, disregard, or distort opponents’ actual positions and beliefs. This was the case, for example, in the article “Ten Reasons Why Reparations for Slavery Is a Bad Idea for Blacks—and Racist Too” (2001) by the conservative activist and media personality David Horowitz.

After Horowitz’s article was published, a sharp encounter ensued between Horowitz and several others involving the definition of “reparations for slavery” and whether it was justified or fair to white Americans currently living and paying taxes. None of the parties to the discussion, on either side, had carefully reviewed the literature or provided any original opposing or clarifying analysis. Thus, the entire episode primarily illustrated the tendency toward carelessness in thought and discussion on racial redistributive justice, even by most proponents. This encounter also underscored the highly emotional quality of much discussion of the subject of reparations, which brings to the surface fundamental, and long-buried and unarticulated, core racial concerns on all sides. The debate also raises questions about the political feasibility of reparations, whatever the term means. Is there broad support for a practical policy and program of explicitly redistributive and compensatory justice in the United States?

There is a growing scholarly analytical literature on the subject of reparations. Among the earliest articles was one by Robert Browne, published in 1972 in a special issue of the Review of Black Political Economy. This issue featured the first attempts to quantify the present value of the stream of benefits to whites from past wrongful takings under slavery, segregation, and discrimination. Much of that analysis was based on work done by the economist Lester Thurow in his 1969 book Poverty and Discrimination. Thurow developed a model, and using census data he established that white Americans gained approximately $15 billion in one year, 1960, from racial discrimination in the labor market.

From 1985 to 1990, the National Economic Association, an organization of African American economists and policy analysts, conducted sessions on reparations at their annual meetings. The papers presented at these sessions were published in The Wealth of Races: The Present Value of the Benefits of Past Injustices (1990), edited by Richard F. America. This volume included the work of William Darity, Roger Ransom and Richard Sutch, Warren Whatley and Gavin Wright, Larry Neal and Robert Browne, and other established economists, and carried quantitative and historically based analysis several steps forward. In a 1993 monograph Richard America continued to refine and develop the concept of reparations, focusing on unjust enrichment and the income and wealth-transfer effects of slavery and discrimination. In 2003 Darity and Dania Frank published a short but comprehensive summary of research to date. This volume
refines the analysis and points to a new framework that can produce an even more robust analytical basis.

A common question raised about reparations is that if they are suitable for African Americans, are they not also appropriate for other aggrieved groups? Responses vary widely. But the emerging approach with the deepest analytical grounding involves an analysis of wrongful taking and unjust enrichment, and findings of magnitudes of compensation based on historical auditing. This approach can be used for other groups with similar historical backgrounds, wherever appropriate.

What about popular opinion and support for or opposition to reparations for African Americans? Michael Dawson and Rovana Popoff (2004) found that 79 percent of blacks and 30 percent of whites in the United States favored an apology for slavery, but 66 percent of blacks and only 4 percent of whites favored monetary reparations to blacks “for slavery.” This finding may or may not reflect actual views on reparations when defined differently as “recapture of unjust enrichment” rather than reparations “for slavery.” That distinction is crucial. The question of reparations, in various forms, has become a serious public policy issue since it first emerged in the late stages of the civil rights movement of the 1960s. Of course, as early as the American Revolution, some advocates of abolition were framing remedies that included some form of compensatory justice for freedmen and freedwomen.

The concept of reparations varies according to the worldview of those in the debate. There are three broad views. For some, reparations primarily mean compensation for the slave trade. A second view is that reparations are owed to current generations for the pain and suffering of their collective ancestors—for crimes against humanity. A third view of reparations is narrower and seeks to recapture, recover, and reclaim unjust enrichment that resulted from wrongful takings under slavery, segregation, and many forms of discrimination from 1619 through the present. The focus in this entry is on this third definition.

The idea of unjust enrichment is key, and functions as a useful framework for understanding chronic poverty, poor educational performance, substandard housing, high unemployment, and low income and wealth accumulation among African Americans, as well as persistent black-white disparities in health care, business investment, and competitiveness. These conditions all derive, significantly, from the processes of wrongful taking and unjust enrichment. In addition, these conditions can be measured because they all include a measurable, historically based component. The processes of slavery, Jim Crow segregation, and discrimination were all mechanisms that transferred or diverted income and wealth from blacks as a class to whites as a class, producing unjust enrichment. Reparations, in this view, constitute the proper basis for a well-founded program for rational compensatory public policy. Unjust enrichment and reparations are ways to understand chronic social distress in a long-term historical context. Slavery and discrimination operated in many forms, in every aspect of American life, for 350 years, and this explains much of the current dysfunction. Social problems derive largely from the extraction or confiscation of black property and income by white decision-makers, for white benefit, in millions of daily microdecisions.

The cumulative effect of those wrongful takings produces current unjust enrichment and a range of conditions referred to as affluence and poverty. This situation helps explain the problems we objectively see on the ground, but this fact has been absent from policy discussions. The reparations concept inserts these ideas into the heart of policy analysis, and changes the way problems are viewed and the way policy and programs are created.

There has been widespread and consistent white discrimination against blacks. This behavior has been unlawful in the United States since 1965, but policy analysts and social scientists have not failed to note the full long-term consequences, especially the unjust enrichment. Explicitly accounting for the ways in which black and white ancestors behaved puts a spotlight on the transferred income and wealth. The concept of reparations, and the associated framework of wrongful taking and unjust enrichment, provides a public policy framework for examining objective reality by quantifying and taking into full account historical context. In this way, it is a new or, at least, improved paradigm—a new or improved way of viewing the world. There has been massive, systematic exploitation and confiscation. And those practices—slavery and discrimination—produced wrongful benefits that have been passed on, transferred intergenerationally, to the present.

This analysis points to redistributive justice—recovering monies wrongly taken through restitution—as the general remedy. That is what reparations mean in public policy terms. Other analysts emphasize payment for pain and suffering or for crimes against humanity. And still others have focused on a form of reparations as a means of laying the groundwork for atonement and reconciliation; they emphasize healing.

But reparations of the kind described here focus on improved public policy analysis, in which national tax and budget priorities are informed by the concept of unjust enrichment, and, by implication, reparations. Thus, social spending becomes a tool for explicitly making restitution.

The amount of reparations owed would equal the net present value of the sum of the deviations from “fair” standards in prices, wages, rents, employment, interest, and investment in education, plus all other affected transactions between whites and blacks. This is an overly simple
but illustrative form of the model that leads to a grasp of the dimensions of the wrongful taking and unjust enrichment that produced the need for reparations. We can audit the actual patterns of labor, trade, and investment relations long after the fact. We can also posit a set of “fair” wages, occupational distributions, employment levels, prices, rents, interest rates, educational expenditures, taxes, profits, and returns on investment. We can then estimate the deviations from those “fair” standards. And we find that those deviations resulted, in part, from force, manipulation, and coercion. Then we aggregate, compound, and adjust for price changes over time. That produces a “bill” that represents the financial basis for redistributive justice. We can then negotiate the bill, and reach rational, feasible, make-whole settlement agreements that will restore African Americans as a class to their rightful place. These actions are reparations. Clarifying that will help clarify policy choices in education, housing, employment, and every other controversial sector. The remedy is income and wealth redistribution in capital injections, or grants, in housing equity, quality education, and business equity, targeted to rectify the injustice.

Reparations are a way of looking at complex policy issues that can be rationally applied to understanding, defining, and solving chronic social problems in housing, health, education, employment, and business and community development. Without this historical framework, public policy cannot effectively address these problems.

REPATRIATION

From the Latin for “fatherland” (patria), repatriation literally means to return, voluntarily or involuntarily, to one’s homeland. The term now has two distinct meanings: either the return of people to their homeland, or the return of cultural objects to their place of origin. The repatriation of people, for example after a war, has a long history, whereas the repatriation of cultural objects, typically the cultural artifacts of aboriginal communities, is associated with postcolonialism, the social movements of native peoples, and the changing function of museums in modern societies.

The repatriation of peoples is closely associated with the growth of national citizenship, the involvement of civilians as victims of modern warfare, and the development of human rights legislation. After World War II (1939–1945), there were over one million displaced persons in Europe, and in 1950 the post of United Nations High Commissioner for Refugees (UNHCR) was established, a year before the 1951 Refugee Convention. In the first fifty years of its existence, the UNHCR gave assistance to at least fifty million people who have been displaced, both internally and externally, as a result of warfare and civil conflict. With the apparently unstoppable growth in the numbers of refugees in the second half of the twentieth century, the humanitarian protection of refugees led to greater concern by the UNHCR in a right to “return in safety and dignity,” as expressed in a 1989 policy document (Coles 1989). Safety refers to physical security and the entitlement to protection from a forced return. Dignity is to be measured by the quality of life in the location to which displaced persons return voluntarily. In practice, achieving a consensus over safety and dignity between states, refugees, and UN agencies is extremely difficult, often because there is little reliable information about the security of war zones that have been subject to a long period of conflict. The protracted arrangements between five separate organizations and a commission in the 1990s to return Guatemalans to Mexico or the case of 200,000 Tigrayans walking home to Ethiopia against the wishes of UNHCR and the government of Sudan are typical of such political uncertainty.

Any account of the repatriation of cultural artifacts needs to consider the historical development of museums as institutions for collecting the material cultures of aboriginal communities and the ancient world. The expansion of museums in the Victorian period was in part a function of the growth of European colonization and the colonial sense of superiority. Britain’s acquisition of the Elgin Marbles from classical Greece was a notorious illustration of the acquisitiveness of Western classicism and archaeology. Thomas Bruce (1766–1841), the seventh Earl of Elgin, obtained a firman (legal document) from
the Ottoman sultan to remove sculptures from the Parthenon in Athens in 1801. Attempts by the Greek government with the support of the United Nations Educational, Scientific, and Cultural Organization (UNESCO) to repatriate the Elgin Marbles have so far been rejected by the British government.

In addition to plundering the classical world, museum curators were especially interested in the primitive and the exotic as collectable items. This was also the period in which the native peoples of the Western Hemisphere were at their lowest cultural ebb. War and disease had produced a demographic catastrophe, and the cultural heritage of native peoples was removed to museums in policies that amounted to deculturalization. In addition to cultural artifacts, human remains from battlefields entered the medical collections of the U.S. Army and physical anthropologists.

The federal Antiquities Act (1906) prevented the destruction of antiquities on public land in the United States, but allowed free import and export of Native American artifacts. It was not until the repatriation movement of the 1980s and 1990s that there was a fundamental change in the relationships between museums and Native American communities, resulting in the National Museum of the American Indian Act (1989) and the Native American Graves Protection and Repatriation Act (1990). Although this legislation is significant, the demand for sacred and ceremonial materials on the international art market is such that looting from archaeological sites continues to be a serious problem.

REPLICATOR DYNAMICS

The replicator dynamics are part of evolutionary game theory and are especially prominent in models of cultural evolution. Evolutionary game theory uses principles of interactive behavior to explain the emergence of behavioral regularities in organisms forming a population. The results of organisms’ interactions affect their fitness, measured as their ability to reproduce. If one organism is fitter than another, then it is more likely to reproduce than the other. An organism’s offspring inherit its traits. The offspring may differ from the parent in fitness, however, because the offspring’s fitness depends on their success in interactions with their contemporaries. As the population changes, the traits that confer fitness may change, too.

The replicator dynamics explain changes in fitness that arise from changes in a population’s composition. Applications divide a population according to organisms’ behavioral traits, in particular strategies for interacting with others. For instance, in a dispute over food, one strategy may be to fight. Another strategy may be to retreat. A strategy’s consequences are assessed in terms of fitness, or average number of offspring.

A mathematical equation characterizes the replicator dynamics. It applies to a population given simplifying assumptions. They specify four conditions: (1) The population is infinite. Assuming an infinite population makes the relative frequency of an outcome match its probability. (2) An individual in the population has the same probability of interacting with any other member of the population. Pairs of interacting individuals form as if individuals were matched at random. (3) Strategies breed true. That is, if an organism has offspring, its offspring adopt the same strategy it follows. An organism’s fitness equals the average number of offspring following its strategy. (4) Reproduction is asexual. An organism has a single parent and so inherits the parent’s strategy. This condition puts aside the possibility that an organism’s strategy differs from a parent’s strategy because it has two parents with differing strategies. The proportion of individuals following a strategy changes only if some organisms with that strategy are more or less fit than their parents and so reproduce more or less frequently than their parents did.

Brian Skyrms’s (1996, pp. 51–53) notation is used here to present the replicator equation. First, assume that a population evolves in steps from one generation to the next. Using the proportion of individuals following a strategy in one generation, and the strategy’s consequences for their fitness, one may compute the proportion of individuals following the strategy in the next generation. Let \( U(A) \) be the average fitness of a strategy \( A \), and let \( U \) be the average fitness of all strategies. Then the proportion of the population using \( A \) in the next generation equals the proportion of the population using \( A \) in the current generation times the ratio \( U(A)/U \). That is, if \( p(A) \) is the proportion using strategy \( A \) in the current generation and \( p(A) \) is the proportion using \( A \) in the next generation, then \( p(A) = p(A)U(A)/U \). If \( A \) has greater than average fitness, its proportion increases. A little algebra yields the following equation specifying the change from one gener-
ation to the next in the proportion of the population using strategy $A$.

$$p'(A) - p(A) = p(A)[U(A) - U]/U$$

Next, suppose that evolution is continuous with respect to time. Then the population evolves according to this differential equation.

$$dp(A)/dt = p(A)[U(A) - U]/U$$

The equation gives the rate of change in the proportion of the population using strategy $A$. Given that the average fitness of the population is positive, the following simpler differential equation describes the structural features of the population's evolution.

$$dp(A)/dt = p(A)[U(A) - U]$$

This equation characterizes the replicator dynamics. Peter Taylor and Leo Jonker (1978) were the first theorists to formulate the equation (using different notation). Peter Schuster and Karl Sigmund (1983) called it the replicator equation and the pattern of change it describes the replicator dynamics.

Social scientists use the replicator dynamics to construct models of human behavior, for example, models of the emergence of cultural norms. When applying the dynamics to cultural evolution, imitation may replace reproduction as the mechanism responsible for replication of strategies. Because human populations do not satisfy exactly the idealizations of the replicator dynamics, the models the dynamics yield are simplifications. However, in some cases the dynamics may approximate the course of evolution.

Applications of the replicator dynamics look for the emergences of stable behavior. Consider, for example, food sharing in a hunter-gatherer society. This strategy may enhance fitness, propagate within a population, and drive out rival strategies. It may be evolutionarily stable in the sense that once a population adopts it, even if a few organisms with different strategies arrive, those new strategies do not propagate within the population. The stable strategy resists invasion by mutants. A strategy that is evolutionarily stable with respect to the replicator dynamics corresponds to a stable Nash equilibrium in a game representing individuals' interactions.

**REPRESENTATION**

Any major dictionary offers numerous definitions of the term *representation*. This indicates that the concept comprises a range of meanings and usages, depending on the type of discourse in which it emerges, the variety of cultural phenomena to which it may refer, and the philosophical programs and ideological perspectives it is intended to serve. Within the realm of sociocultural studies, two clusters of meanings of the term—defined as the “act or action of representing: the state of being represented” (*Merriam-Webster’s Collegiate Dictionary* 2003, p. 1057)—have acquired critical importance:

1. To bring clearly before the mind (a book that *represents* the character of America); to serve as a sign or symbol of (the flag *represents* a country); to portray or exhibit in art; to serve as the counterpart or image of (a movie hero who *represents* the character of a culture); to describe or depict in language.

2. To take the place of in some respect; to act in the place of or for usually by legal right; to serve especially in a legislative body by delegated authority usually resulting from election. (*Merriam-Webster’s Collegiate Dictionary* 2003, p. 1057)

Both clusters of meaning suggest that representations essentially stand in for something or someone else, and, as such, present something or someone a second time—they literally re-present. Although it is fair to say that representation functions through reproduction (for example, most people in the Western world are familiar with the image of Rembrandt’s 1642 painting *The Night Watch*, without ever having seen the original painting, through reproductions), or by processing the likeness of an object, this is not the sense in which the issue of representation has come to prevail in recent theoretical discussions. In the simplest terms, representation in contemporary sociocultural theory is the production of meaning through lan-
guage. As Stuart Hall points out in *Representation: Cultural Representations and Signifying Practices* (1997, p. 17), representation constitutes the link between concepts and language that allows us to refer to objects, people, and events in the "real" world, or to imaginary worlds of fictional objects, people, and events (as in films or literary texts). In this line of thought, representations do not so much stand for some underlying "real," or re-represent some original or preexisting object, as they call into being, in fact quite literally *produce*, that to which they supposedly refer, or re-present.

The philosophical concern with representation dates back to ancient times, with Plato (427–347 BCE) and Aristotle (384–322 BCE) acting as key figures. Plato considered representations—whether musical, literary, or visual—as potentially dangerous, creating illusory worlds that would lead one away from "real things." Aristotle, in contrast, regarded the ability to re-create, through *mimesis* (the imitative representation of nature and human behavior in art and literature), as that which distinguishes human beings from animals, and thus as necessary for people's learning and being in the world. In his influential book *The Mirror and the Lamp* (1953), literary scholar M. H. Abrams argues that the Aristotelian notion of representation in terms of *mimesis* (the supposition that the mind, and its products, reflect the external world) dominated Western attitudes toward representation up to the eighteenth century. The antimimetic approach that emerged with the advent of romanticism subsequently came to substitute the idea of the mind as an essentially passive, reproductive apparatus with the notion of the mind as an active and creative power. Since reality is only accessible through representation—through texts, discourses, and images—there is no unmediated access to reality. The products of the mind, in the form of representations, consequently came to be regarded as so many different and, indeed, active attempts to make sense of the world, as historically and culturally shifting constructions of equally shifting realities, rather than as accurate reflections of preexisting objects, people, and events in the world. Moreover, since reality is always more complicated and therefore necessarily exceeds the ways in which it can be signified by any culturally and historically prevailing means of representation, it remains always necessary to construct new ways of seeing reality, to produce new (modes of) representation.

The productive notion of representation suggests that there is no inherent meaning in any picture or sentence or sound; rather, as Dani Cavallaro posits in *Critical and Cultural Theory*, a representation "only represents by virtue of being interpreted and ultimately represents anything it is capable of suggesting" (2001, p. 39). This entails that, rather than acting individually and exclusively on their own terms, any representation is part of a *system of representation*. First, as Hall argues, there is the system that allows us to sort all kinds of objects, people, and events, in correlation with a set of concepts and ideas that "we carry around in our heads" (1997, p. 17). This system does not so much consist of individual concepts or ideas, but rather of different ways of organizing, arranging, and classifying concepts on the basis of similarity and difference. Representations, therefore, always require interpretation within a specific set of interpretive conventions that make up the dominant way of looking at reality within a culture at a certain time in history. Second, there is the system of language. The conceptual map of reality that is shared by individual people within a given society, and which enables them to make sense of reality, is necessarily mediated by a shared system of signs, a common language of words, images, and sounds. Signs—in the broadest sense, so as to include not only spoken and written languages proper, but also visual images, facial expressions, and body language, as well fashion, music, or any other body of signs that carries and expresses meaning—jointly make up the system of signification and representation, that is, the sociohistorically specific system of organizing reality that helps us to make sense of the otherwise incoherent mass of our everyday experience. Since systems of representation mediate our access to the world, representations are never immediately and unequivocally connected with an underlying reality: We only experience reality through the mediation of texts, discourses, and images. The real as such is unattainable, and may only be grasped according to the codes and conventions of interpretation and signification of any specific society.

Understanding representational practices as the medium or channel through which meaning production happens, most contemporary theorists infer that objects, people, and events in the world do not have fixed or stable meanings, but only acquire meaning within a specific culture, and are defined by human beings, participants in a culture, who speak with a certain authority to make things mean or signify something. At this point, the first and the second cluster of meanings of the term *representation* begin to converge, as well as to show up its ideological and political aspects. Since those who speak with authority about the ways in which (certain aspects of) reality make sense, or signify, and since no representational account of reality can ever fully grasp the complexities of such realities, systems of representation cannot but offer partial and, indeed, interested ways of viewing the world and the people, objects, and events within it. As W. J. T. Mitchell points out in *Picture Theory*, representation not only works to mediate our "knowledge (of slavery and of many other things), but obstructs, fragments, and negates that knowledge" (1994, p. 188). Instead of seeing representations as only particular kinds of objects representing something or someone else, this perspective
asks us to approach representation as an active process and product of power (relations), in which certain kinds of representations are produced, valued, and exchanged on the basis of underlying interests and investments, while alternative ways and conventions of representation are either disavowed or simply negated so as to affect, fragment, or deny other forms of knowledge about the world, and the objects, people, and events within it. As such, particular modes of representation can be seen to offer clues to a given culture’s (dominant) belief systems, its interpretations of reality, and its translations of factual and fictional situations into words and images. Representations, on this view, embody certain kinds of social relations, the interpretations and evaluation of which are necessarily partial, more imaginary than “real,” and always already endowed with specific interests and investments. Rather than objectively reflecting the world as it is, representation thus constructs shifting realities as they are perceived through various, ideologically informed filters and channels.

REPRESENTATION IN POSTColonIAL ANALYSIS
People know and comprehend the complex world in which we live through the act of naming it; thus through language and representations. The term representation embodies a range of meanings and interpretations. Etymologically, representation can be understood as a presentation drawn up not by depicting the object as it is but by re-presenting it or constructing it in a new form and/or environment. In ancient times representation played a central role in studying and understanding literature, aesthetics, and semiotics. The construct has since evolved into a significant component to analyze the contemporary world's creation of audio visual as well as textual arts, such as films, museum exhibitions, television programs, photographs, paintings, advertisements, and literature. None of these representational forms are neutral because it is impossible to divorce them from the culture and society that produces them. R-rated films are an example of cultural restrictions, highlighting society's attempt to control and modify representations to promote a certain set of ideologies and values. Despite these restrictions, representations have the ability to take on a life of their own once in the public sphere. The term representation cannot be given a definitive meaning because there will always be a gap between intention and realization, original and copy.

In a 1997 essay entitled The Work of Representation, the sociologist Stuart Hall discusses the relationship between politics and representation and the systems representing both. He approaches representation as the medium or process through which meaning, associations, and values are socially constructed and reified by people in a shared culture. Representation involves understanding how language and systems of knowledge production work together to produce and circulate meanings. According to Hall, we give things meaning by how we represent them. Cultural representations help form the images people have of others; if assimilated by those others, they help form the images people have of themselves as well; cultural representations get embodied in institutions and inform policies and practices. The politics of representation, then, revolve around issues of power and control over one's own self and its representations and reproduction by others.

In sociocultural representations it is often difference that signifies by creating binary oppositions. Within this dichotomized relationship, one pole always tends to dominate (e.g., male over female, us over them, high over low), bringing issues of dissimilarity and power to the fore within a representation. The act of unreflexively representing the other has significant resonances with long-standing practices of domination within the context of colonization. A heightened awareness that asymmetries of
representation enacted and reproduced the asymmetries of power in the colonial world has enhanced the significance of cultural politics in the academic field of postcolonial studies. The focus on culture and representation is not necessarily a diversion from the political realities of postcolonial struggle; culture and representation can even be used to inform the understanding of those colonial processes.

Much postcolonial scholarship is informed, in one way or another, by theories that elucidate the politics of representations. The single most influential scholar demystifying the process of constructing “the Other” is Edward Said (1935–2003). Employing a Foucaultian conception of the power/knowledge nexus and the politics of representation, Said’s seminal book *Orientalism* established how the “West” (especially Britain, France, and the United States), through an academic, literary, and philosophical endeavor executed by Western intellectuals, was able to manage—and even produce—the Orient politically, sociologically, militarily, ideologically, scientifically, and imaginatively during the post-Enlightenment period (an era initiated by colonial conquest). This linear and uninterrupted construction of the Orient as “Other” over many centuries became the basis and rationale for colonial oppression and served to strengthen the identity of Western culture. In Said’s words, “Orientalism is—and does not simply represent—a considerable dimension of modern political-intellectual culture, and as such has less to do with the Orient than it does with ‘our’ world” (Said 1994, p. 12).

Said eloquently demonstrated how the representations of Orientalism pervade the writings of European and North American literature icons such as Charles Dickens, Jane Austen, Henry James, and Thomas Hardy as well as modern-day media reports about the developing world, particularly the Islamic world. Although Said’s arguments have been challenged and extended, his work is still the governing voice that leads scholars in anthropology, literature, mass communication, and postcolonial studies to critically analyze representations that demarcate “us” versus “them.” Said’s insights provide a handy toolbox with which one can easily demystify how the global media exacerbated the stereotyped conflict between the West and the Islamic world in the post 9/11 era.

The postcolonial scholar Gayatri Spivak made an important contribution to theories of representation by insisting that the concept in a literary or semiotic sense must be reconsidered in connection with representation in politics, representation in the sense of any capacity for a person to be the agent of, or stand for, the will of other people. In her provocative essay *Can the Subaltern Speak?*, Spivak underlined how representations, especially of marginalized groups from developing countries, are intimately linked to positioning: socioeconomic, gendered, cultural, geographic, historical, and institutional. The crux of Spivak’s argument is that the representations of the developing world conflate two related but discontinuous meanings of representation (Spivak 1988, pp. 275–276). One meaning is “speaking for,” in the sense of political representation, and the second is “speaking about” or “re-presenting,” in the sense of making a portrait. While Spivak recognizes that representations cannot escape “othering,” Spivak argues for us to be scrupulous in so doing, especially in the case of unequal power relationships, when representing the West’s Other (the developing world) and the developing world’s Other (the subaltern).

Awareness of the constructed nature of sociocultural representations does not mean that people can do without them. A way to bypass the dilemma of representation of and for others is to acknowledge and articulate how power enters into the process of cultural translation. In the end, the crisis of cross-cultural representation can be resolved only through cross-cultural communications that are actually, rather than virtually, decentered and multivocal, that is, through the empowerment of others to participate as equal partners in the conversation of humankind.

**REPRESENTATIVE AGENT**

The representative agent is a device used by economists to model the macroeconomy. The general idea is to solve a well-specified microeconomic problem, and then use the relationships between the variables in that model as a description of the macroeconomy. For example, we can model the decisions that would be made by a person who...
would like to consume goods and enjoy leisure, but can only purchase goods after earning wages through working. Additionally, we can posit a specific production technology that determines how many goods are produced when the person works. From this problem, we can solve for the relationship between the state of the economy and the person's decision on how much to work and consume. A representative agent model would then take these relationships, which were derived for an individual, and use them as an exact specification of the macroeconomy. Thus, if the representative agent would increase consumption by 10 percent in response to a 5 percent increase in the level of technology, it is assumed that aggregate consumption will also rise by 10 percent in response to the same change.

The earliest form of a representative agent was in Alfred Marshall's *Principles of Economics* (1890). Marshall constructed a representative firm as a means of specifying an industry supply curve. This representative firm was vigorously criticized by economists at the time, and the notion vanished from economics.

Representative agent models were resurrected by macroeconomists in the 1970s and became the predominant means of studying the macroeconomy in the 1980s. Surprisingly, nobody has ever written an explicit defense of this technique. The underlying rationale seems to be a desire to provide microfoundations for macroeconomic research. If we acknowledge that macroeconomic relationships are the result of a vast number of decisions made by individuals, then it might be desirable to have our macroeconomic models derived from relationships found in microeconomic problems. Because it is impossible to model the decisions of every individual in an economy separately, some shortcut is needed. Hence the representative agent is a stand-in for an average person, and the macroeconomy is assumed to behave, on average, like the average person.

Representative agent models have been roundly criticized as being an improper means of studying the macroeconomy for several reasons. It is simply not the case, even in very simple economies, that the aggregate of many decisions is exactly the same as the decision made by the representative agent. Representative agent models are incapable of capturing the effects of heterogeneity and interaction among agents, nor can they capture the effects of problems related to asymmetric information or strategic interactions. Fundamentally, representative agent models suffer from the fallacy of composition (that what is true of the part is true of the whole). The extensive criticisms demonstrating that representative agent models are neither good nor useful means of studying the macroeconomy have never been addressed by those who use such models. Yet, the use of the representative agent model continues apace.

**REPRESSION**

Repression is the use or threat of actions taken by state “authorities, or their supporters, against opponents or potential opponents to prevent, weaken, or eliminate their capacity to oppose policies” (Stohl and Lopez 1984, p. 7). Authorities include security forces and paramilitaries that target groups or individuals because of “their perceived political beliefs” (Goldstein 1978, p. xvi). Repression is associated with the related but distinct phenomena of terror, violence, and oppression.

Terror and violence describe actions by authorities against political opponents or by insurgent groups in their own campaigns against the incumbent government. The distinguishing characteristic is the perpetrator. State terror is a strategy of repression to instill fear and quiescence in the entire population. Violence by the state is also repression.

Oppression and repression are distinct but may occur together, such as with the policies of the white apartheid government in South Africa from 1948 until 1990. The apartheid system denied civil and political rights and economic and social privileges to the black South African majority as a matter of government policy (oppression). Nelson Mandela, a political prisoner for almost thirty years and leader of South Africa’s black-majority African National Congress, was also the target of repression, including torture during his imprisonment.

Common examples of repression are media censorship, surveillance of political meetings, the suspension of habeas corpus, the banning of political parties, and the violation of due process rights (e.g., illegal searches and arbitrary arrests). Some restrictions may be ostensibly nonviolent, like censorship. Violent repression is sometimes called a personal integrity violation because it violates bodily and personal autonomy. Examples are torture, disappearances, and extrajudicial killings by security forces and paramilitaries associated with military governments.
where civilian rule is suspended or abolished. This type of repression occurred under the Argentine military junta during the “Dirty War” (1976–1983) against Peronists, labor leaders, and other civilians.

Well-known examples of violent repression include the genocide of six million Jews, along with dissidents, Catholics, and countless others, by the German Nazi government (1930s to 1940s); forced collectivization under Joseph Stalin (1879–1953) in Soviet Russia in the 1940s; and the Cultural Revolution (1966–1976) in China under Mao Zedong (1893–1976). The 1980s were marked by extensive disappearances and killings by military regimes in Guatemala and El Salvador that targeted indigenous groups, whether or not they were politically mobilized.

Constitutional or emergency provisions may provide a legal character to such actions as detaining people (without charge) suspected of political violence, conducting surveillance on radical groups, or banning political parties accused of threatening political stability. Legal prohibitions may be codified into statutes to restrict political behavior or reconstitute political quiescence. For example, in the 1980s the Polish Communist government imposed martial law and banned the politically mobilized labor organization Solidarity to avert a Soviet intervention. In Germany, *Mein Kampf* (My Struggle, 1925–1926), an anti-Semitic political manifesto by Adolf Hitler (1889–1945), has been banned to prevent the expression of fascist ideology. Legal repression, especially in democracies, is not necessarily legitimate behavior and is often admonished by citizens, world leaders, and human rights organizations.

Repression in the form of repressive tolerance puts pressure on unpopular political minorities to conform to majoritarian views. This may occur under democratic governments along with surveillance of political groups. For example, the U.S. House of Representative’s Un-American Activities Committee (HUAC), active from 1945 to 1975, targeted the American Communist Party and its supporters during the tenure of Senator Joseph McCarthy (1908–1957). Similarly, J. Edgar Hoover (1895–1972), director of the Federal Bureau of Investigation (FBI), established the covert COINTELPRO (counterintelligence program) in 1956 using the FBI to monitor communists, civil rights leaders, and political activists like Martin Luther King Jr. (1929–1968), Malcolm X (1925–1965), and Huey P. Newton (1942–1989) of the Black Panther Party. COINTELPRO operations lasted until 1971, when Hoover officially disbanded the program in anticipation of congressional investigations.

No ideological system evinces exclusive association with repression, although healthy debate exists over this issue. Different patterns are identified within certain political historical contexts. Some scholars argue that in the United States and historically, groups representing leftist ideas, such as labor, student movements, and the more radical Black Panther Party, were targeted much more than violent groups on the extreme right, such as the Ku Klux Klan. News media and other scholars have produced equally extensive documentation on Soviet and Chinese Communist repression against their own populations. For example, the secret police in the Soviet Union imprisoned political dissidents and used surveillance and propaganda for the duration of the twentieth century. The Chinese government killed many prodemocracy demonstrators in the Tiananmen Square massacre in 1989.

Claims are advanced on each side of this ideological debate, backed by historical evidence in books, reports, and other material. A more tenable position is that no clear affinity exists between repression and the ideological orientation of government. Repression has been used against internal political opponents by communist (leftist), fascist (rightist), and even democratic governments.

REPRESSIVE TOLERANCE

In the essay “Repressive Tolerance” (1965), the German-born American critical theorist Herbert Marcuse (1898–1979) of the Franklin School of political theorists argued that, under the conditions of advanced industrial capitalism, the only hope for realizing the original objectives of “liberalist” or “pure” toleration (as articulated by the British philosopher John Stuart Mill [1806–1873])—freeing the mind to rationally pursue the truth—was to practice a deliberately selective “liberating tolerance” that both targeted and enacted the repression alluded to in the essay’s paradoxical title (Marcuse 1965, pp. 81, 85, 90). This “liberating tolerance” would involve “the withdrawal of toleration of speech and assembly from groups and movements” on the Right, and the aggressively partisan promotion of speech, groups, and progressive movements on the Left (pp. 81, 100).

Marcuse professed to share liberalism’s belief in human rationality and objective truth, and a commitment to its core mechanisms, including toleration. Following G. W. F. Hegel (1770–1831), however, Marcuse insisted that the meaning and logic of ideas, concepts, and principles cannot be determined abstractly, but instead are dialectically conditioned by the totality of the historical epoch in which they are practiced. Following Karl Marx (1818–1883), Marcuse insisted that domination was the central social fact and the most important moral and political problem, and that a humane society of genuinely free and equal individuals living “without fear and misery” is history’s telos (Marcuse 1965, p. 82). And, following Sigmund Freud (1856–1939), Marcuse conceded that, in any civilized society, intractable conflicts would necessitate the suppression of important human desires. Nevertheless, Marcuse argued that developments in the political and cultural economies of the affluent, post–World War II (1939–1945) liberal capitalist societies had ushered in new forms of domination—“surplus repression”—that placed intolerable fetters on human freedom (Marcuse 1955). In the process, they had undermined the basis of both economic and political liberalism and “the liberal function of tolerance” (Marcuse 1965, p. 115). The practice of a liberating tolerance was the only hope for its restoration.

“The function and value of tolerance,” Marcuse explained, “depend on the equality prevalent in the society in which tolerance is practiced” (Marcuse 1965, p. 84). Driven as they are by the engines of advertising, propaganda, and militarism in the service of ever-increasing affluence, advanced liberal capitalist societies are defined by their inequality. Moreover, their dominant social institutions, including the “monopolistic media,” use new and dystopian forms of “technological and mental coordination” to administer what has become a “totalitarian,” self-perpetuating system (pp. 94, 95, 97). In these societies, where “the economic and political process is subjected to an ubiquitous and effective administration in accordance with the predominant interests,” individuals have been systematically divested of their capacity to think as rational, autonomous individuals (p. 115). As such, they have lost their capacity to pursue truth through the free exercise of their individual reason, and, in turn, to create a just and humane society.

In a “democracy with totalitarian organization,” the administration is so permeating that it comes to define consciousness itself (Marcuse 1965, p. 97). Far from serving as a neutral medium for rational reflection, the language, its very concepts and categories, is transformed into a neutralizing instrument of repression. Through the operation of language, “mental attitude[s]” are formed that tend to “obliterate the difference between true and false, information and indoctrination, right and wrong” (p. 97). People “are indoctrinated by the conditions under which they live and think and which they do not transcend” (p. 98). We observe “the systematic moronization of children and adults alike by publicity and propaganda” (p. 83). The populace is incorporated into “a system which fosters tolerance as a means of perpetuating the struggle for existence and suppressing the alternatives” in significant part by “testifying to the existence of democratic liberties” (pp. 83, 84). The society’s ceaseless congratulation of itself for its commitment to “the marketplace of ideas” acts as an opiate on the mass consciousness, turning individuals away from radical possibilities and reconciling them to the status quo (p. 110). While the toleration of ostensible dissent is celebrated, truly “effective dissent” becomes impossible (p. 95). Under these historical conditions, the purportedly neutral “liberalist” tolerance becomes repressive (p. 90). To weigh truth and falsity rationally and accurately, to be in practice the rational and autonomous beings that Mill envisioned,
individuals first need to be “freed from the prevailing indoctrination” (p. 99). For this reason, affirmative, partisan steps slanted to the Left are needed to liberate individuals and to restore their ability to reason.

“The efforts to counteract this dehumanization,” Marcuse explained, “must begin at the place of entrance, there where the false consciousness takes form (or rather: is systematically formed—it must begin with stopping the words and images which feed this consciousness)” (Marcuse 1965, p. 111). To be liberated, individuals “would have to get information slanted in the opposite direction” (p. 99). The withdrawal of tolerance would have to be aimed at ideas, groups, and movements “which promote aggressive policies, armament, chauvinism, discrimination on the grounds of race and religion, or which oppose the extension of public services, social security, medical care, etc.” (p. 99).

Marcuse’s call for “the restoration of freedom” through the practice of liberating tolerance raised the question of “who is to decide on the distinction between liberating and repressive, human and inhuman teachings and practices” (Marcuse 1965, p. 101). Rejecting relativism, he maintained that these distinctions “can be made rationally on empirical grounds” by “everyone who has learned to think rationally and autonomously” (pp. 105, 106). Who would these clear-sighted leaders be, and how many could we expect to find? “Where society has entered the phase of total administration and indoctrination,” he noted, “this would be a small number indeed, and not necessarily that of the elected representatives of the people” (p. 106).

Marcuse was often pessimistic about the prospects of a widespread liberation from “the false consciousness [that] has become the general consciousness” (Marcuse 1965, p. 110). But in “Repressive Tolerance,” he appealed hopefully to engaged intellectuals whose “task and duty … [is] to recall and preserve historical possibilities which seem to have become utopian possibilities,” and “to break the concreteness of oppression in order to open the mental space in which this society can be recognized as what it is and does” (pp. 81–82).

Marcuse insisted that, unlike in the spheres of business, advertising, and the broader culture, “the trend in the educational enterprise … could conceivably be enforced by the students and teachers themselves, and thus be self-imposed” (Marcuse 1965, p. 101). “The restoration of freedom of thought,” of course, may necessitate new and rigid restrictions on teachings and practices in the educational institutions which, by their very methods and concepts, serve to enclose the mind within the established universe of discourse and behavior—thereby precluding a priori a rational evaluation of the alternatives. Restoration of such freedom would also imply intolerance toward scientific research in the interest of deadly “deterrents,” of abnormal human endurance under inhuman conditions, etc. (pp. 100–101)

“Unless the student learns to think in the opposite direction,” Marcuse insisted, “he will be inclined to place facts into the predominant framework of values” (p. 113). Under these historical conditions, all genuine education is “counter-education” (p. 112).

Marcuse’s call for a liberating tolerance was adopted enthusiastically by the radical student movements of the late 1960s in both Europe and the United States, and was particularly influential on the American New Left. His argument that a vanguard of students, teachers, and intellectuals had a special role to play, especially within educational institutions, of “break[ing] the concreteness of oppression” by suppressing ideas and actions (and language) objectively determined to be “regressive” and “inhumane” with the object of freeing students from “the prevailing indoctrination” and reestablishing the conditions of equality conducive to true freedom, played a major role in reshaping the mission and practices of the contemporary “politically correct” multiculturalist college and university (Marcuse 1965, pp. 81, 101, 99).

As liberalism and leftism made common cause in the historical crucible of the late 1960s and the 1970s, the Marcusian approach to tolerance insinuated itself—if not always self-evidently in theory, then more transparently in practice—into even ostensibly mainstream or “pure” liberal thinking (the thought of libertarians excepted), as well as into the governing rules and practices of institutions, such as universities, under liberal-left control. Whether this marks a departure from liberal principles, or (as Marcuse maintained) a return to liberalism’s traditional historical function, is a question of considerable interest and complexity.

REPRODUCTION

“Reproduction” in anthropology refers to the processes by which new social members are produced—specifically, the physiological processes of conception, pregnancy, birth, and child-raising. In its larger sense, reproduction encompasses the processes by which societies are reproduced for the future. The term is thus fraught with biological, cultural, and political meanings; power is a central focus in reproductive studies, as those who have the power to influence the process of reproduction can control both individual and large populations for better or for worse.

The maturation of the field of the anthropology of reproduction was marked by the publication of Conceiving the New World Order: The Global Politics of Reproduction (1995), edited by Faye Ginsburg and Rayna Rapp. This collection expanded the meaning of reproduction into the political arena and generated the interface of reproductive studies with wider issues in the politics of women's health care. From a study of anti-abortion policies in Romania, to China's one-child policy, to the displacement of thousands of women in India and Pakistan to “purify the national bodies” of both countries, the chapters in this volume called attention to the impact of national and global processes on everyday reproductive experience, most especially through the notion of “stratified reproduction,” which points to transnational reproductive inequalities based on gender, race, and class. In addition, Rapp's long-term fieldwork on amniocentesis illustrates racial, class, and religious differences in how women make choices about this technology, and demonstrates the linguistic power of genetic counselors to influence these choices in favor of the culturally approved choice of abortion for genetically defective babies.

Since the 1990s, most anthropological studies of reproduction have focused on what have come to be called “the new reproductive technologies” (NRTs)—technologies designed to intervene in human reproduction. From the birth of the world's first test-tube baby in 1978 to the cloning of a higher vertebrate from an adult cell in 1997, the rapid expansion of the NRTs in the latter half of the twentieth century dramatically redefined the parameters of biological reproduction. The NRTs include, among many others: birth control technologies such as intrauterine devices (IUDs) and the birth control pill; assisted conception technologies such as artificial insemination and in-vitro fertilization (IVF); screening technologies such as ultrasound, amniocentesis, and blood testing; reparative technologies such as fetal surgeries performed in utero; labor and birth technologies such as electronic fetal monitoring, synthetic hormones for labor induction and augmentation, and multiple types of anesthesia; and postnatal technologies such as infant surgeries and high-tech treatment of babies in neonatal intensive care units. All of these technologies are increasingly affected by developments in biotechnology, such as genetic engineering, which have major implications for the control and management of human fertility.

Like the obstetrical forceps developed by the Chamberlen brothers in the sixteenth century, the NRTs have double-edged implications for women and their offspring. While those early forceps did save the lives of babies who otherwise might have died, their overzealous and ill-informed application during childbirth by male midwives and obstetricians often left the mother and baby severely damaged. The NRTs have been equally problematic, often creating as many problems as they solve and causing as much damage as they repair. For example, maternal mortality as a result of ovarian hyperstimulation, and increased congenital abnormality because of multiple births, are but two examples of the downside of in-vitro fertilization (IVF).

Reproductive technology has affected every facet of the reproductive process, from preconception onward. To an extent, these developments respond to specific impediments to fertility: IVF, for example, was originally used to assist women with blocked ovarian tubes. Feminist critics, however, have rightly pointed to other, less woman-centered influences shaping the development of these technologies. For example, Robert Edwards, the research scientist who helped to develop IVF, was trained in embryology and foresaw tremendous research potential from the ability to manipulate the human embryo ex vivo. This potential was extensively exploited in the rapid expansion of human embryo experimentation in the 1980s and the 1990s.

The encounter between a largely male medical and scientific establishment and women's reproductive capacity is very pointed in the context of IVF, which is often represented as being a response to the “desperate” desires of infertile women but can as readily be interpreted as a response to the irresistible scientific urge to “unveil” and indeed to redesign “the facts of life.” The tremendous value of early embryonic cells—both commercially and in terms of research—has made IVF an important source of human embryonic stem cells. This fact exists in uneasy tension with women's demands for improved reproductive services. As in other historical periods, the neglect of women's reproductive needs is most evident in terms of which kinds of services will be developed and prioritized.

While new embryo therapies are used to detect, and even to eliminate, genetic disease, other reproductive priorities remain devalued and underfunded. For example, while ever more sophisticated technologies are developed to deal with the complications of labor and birth, the normal physiological needs of laboring women remain understudied and unfulfilled. The scientific evidence that does
exist supports simple technologies like eating and drinking during labor, woman-centered, supportive care, and upright positions for delivery as being of far more help to birthing women than high-tech machines. Nevertheless, the hegemonic global influence of what Davis-Floyd (2004) calls “the technocratic model of birth” has resulted in rapidly rising cesarean rates in many countries and has simultaneously precluded adoption of more humanistic and physiologic techniques for supporting normal birth. A growing body of anthropological literature reveals the systematic deconstruction of traditional birthing systems around the world. These systems are being replaced by biomedical care that disregards women’s individual needs in favor of standardized approaches (DeVries et al. 2001), and that, in the developing world, often suffers from such drastic underfunding that basic supplies, clean facilities, and sufficient numbers of trained caregivers are regularly unavailable (Allen 2002; Davis-Floyd and Sargent 1997; Feldman-Solvesberg 1999; Hunt 1999; Luckere and Jolly 2002; Ram and Jolly 1998; Van Hollen 2003).

Two major influences continue to shape the development of reproductive technology in ways that are not in women’s interests. One is the continuing, and indeed worsening, effects of global inequality that are borne most heavily by women and young children, especially infants. Adequate, or indeed any, access to basic contraceptive technology remains out of reach of the majority of the world’s female population (despite concerns about population growth, and largely as a result of U.S. anti-abortion policy). Consequently, resource-intensive and largely private fertility care is provided to a predominantly wealthy world elite. Meanwhile, enduring tragedies of high maternal and infant mortality from preventable causes such as malnutrition and lack of a clean water supply, inadequate access to safe abortion and contraceptives, and limited, nonexistent, or ineffective reproductive health care are the main issues affecting the majority of the world’s women. In sum, proper sanitation, adequate nutrition, improved vaccination programs, access to culturally appropriate forms of birth control, access to community midwives backed by adequate transport systems, and above all increased literacy and education rates among women remain the most important and lifesaving “reproductive technologies.”

At the other end of the spectrum, at the cutting edge of twenty-first-century medical science, is the resurgence of a new genetic essentialism. Reproductive technology is shifting its focus in the direction of germline gene therapies (therapies that can be genetically transmitted because they modify reproductive cells). Annexed to the project of mapping the human genome, reproductive science and medicine are increasingly aimed at both the elimination of genetic pathology and the effort to reengineer the genomes of humans and other life-forms. In addition to existing means of technologically assisting conception, the effort to alter human genealogy is the single most important influence on contemporary reproductive technologies. This effort is driven by enormously competitive economic forces and by an “if we can do it, we must do it” technocratic mentality, resulting in rapidly escalating and largely unregulated technological innovation.

While some commentators argue that reproductive technologies such as the freezing of eggs, cloning by nuclear transfer, germline gene therapy, and embryo biopsy will have a radical effect on gender roles and kinship definitions, the majority of evidence demonstrates a reverse effect: the restabilization of traditional and conservative family ideologies in the face of their potential disruption. At the same time, other influences, such as the lesbian and gay movement, the increase in transnational adoption, rising divorce rates, and greater economic independence for women, have proven more influential in the redefinition of family and parenthood. Consequently, although some uses of reproductive technology have created more parenting options, such as the use of artificial insemination by lesbians, the overwhelming pattern of access to NRTs is defined by the goal of enhancing conventional parenting arrangements by married, heterosexual, and middle-class couples.

Feminist concern about reproductive technologies in the twenty-first century will increasingly overlap with the criticisms of biotechnology and genetic engineering raised by environmentalists and the general public. Concern about genetically modified organisms in the food chain and in medical applications will increase, particularly as the human-animal border becomes ever more permeable. The extensive feminist literature on NRTs anticipates with great precision many of the profound social, ethical, and political concerns surrounding new forms of genetic and biological determinism arising out of the attempt to alter the human genome. In addition to the effort to redefine medical and scientific priorities in relation to women’s reproductive health worldwide, feminist anthropological scholarship will continue to insist upon the primacy of fully informed reproductive decision making, in its widest sense, as a fundamental component of human rights.

REPRODUCTIVE POLITICS

Reproductive politics address fundamental values relating to highly personal topics, such as sexuality, marriage, bodily integrity, and the definition of life. Specific topics addressed are drawn from the steps in human reproduction (sexual intercourse, conception, gestation, and parturition) as well as the major interventions in fertility control (abstinence, contraception, and induced abortion). Because only women become pregnant and bear children, reproductive politics necessarily reflect attitudes and social mores about the role of women. While reproductive politics in the United States became particularly fierce after the 1973 Roe v. Wade decision, the state’s role in reproductive behavior has been debated for considerably longer.

At the beginning of the nineteenth century, reproductive matters were largely outside of American politics, but contraception and induced abortion were legal. Puritan disapproval of birth control as well as other social conventions kept these subjects out of the realm of politics. By the end of the century, both contraceptive practice and induced abortion had been outlawed in every state. Physicians led the way in passing state anti-abortion legislation, but opposed contraceptive restrictions. In 1873, Congress passed the Act for the Suppression of Trade in and Circulation of, Obscene Literature and Articles of Immoral Use. Known as the Comstock law, the act prohibited interstate trading in any article that prevented conception or caused abortion. Twenty-two states followed with even more contraceptive restrictions, called the “little Comstock laws.”

Removing nineteenth-century prohibitions was a major part of reproductive politics during much of the twentieth century. The most influential birth control crusader was Margaret Sanger, founder of the American Birth Control League, which eventually became Planned Parenthood Federation of America. By 1937, the birth control movement had orchestrated and won the U.S. v. One Package case, which largely invalidated the federal Comstock law. It was 1965, however, before the U.S. Supreme Court overturned Connecticut’s Comstock law prohibiting the use of birth control by even married couples (Griswold v. Connecticut) and 1972 before the Court invalidated the Massachusetts law specifically prohibiting unmarried persons from obtaining contraceptives (Eisenstadt v. Baird). In the 1973 Roe v. Wade decision, the Court legalized abortion.

Roe v. Wade ignited interest group activity in reproductive politics. There are many advocacy groups in this arena, including the NARAL Pro Choice America (pro-choice or favoring the legal status of abortion) and National Right to Life (pro-life or opposing the legal status of abortion). Their debates have expanded far beyond the legal status of abortion and now focus on policies toward welfare, scientific research, custody of offspring, international humanitarian assistance, and a variety of other subjects. These topics are best framed within steps in reproduction.
STEPS IN REPRODUCTION
Except for artificial insemination and in vitro fertilization, the first step in human reproduction is sexual intercourse. Within reproductive politics, who should be sexually active and with whom are active debates. Religious conservatives believe that heterosexual marriage is the only suitable context for sexual activity; their growing political involvement has spawned significant federal support for abstinence-only education and the ABC (Abstain, Be faithful, or use Condoms if you cannot follow A or B) policy in HIV/AIDS prevention. Opposing groups argue for accurate, comprehensive sex education that includes contraceptive information, pointing out that the effectiveness of abstinence-only education has not been demonstrated and that most people are sexually active years before marriage.

Conception is the second step in human reproduction. The politics regarding it include both contraception and fertilization. Here there are differing viewpoints concerning who should have access to birth control, what methods are appropriate, and how to pay for contraceptives. The provision of contraception to minors is hotly debated, particularly whether there should be mandated parental involvement (e.g., permission or notification). The politics around available methods include the U.S. Food and Drug Administration (such as delays in the approval of over-the-counter emergency contraception) and product liability laws, which have limited contraceptive options in the United States. Political issues around fertilization include who should have access to assisted fertility technology (such as single women, married heterosexual couples, persons under a certain age) and how fertilized eggs can be used (for example, stem cell research and embryo adoption).

The third step in human reproduction is gestation and parturition. The dominant issue here is induced abortion or pregnancy termination. Abortion brings up a number of policy issues such as parental involvement, mandatory waiting periods, informed consent, funding, allowable procedures (such as partial birth abortion, which is a political term from the Christian Coalition, not a specific medical procedure) pharmaceutical abortifacients, and gestational limits. Many of these policies vary widely among the states.

Other political issues related to gestation include violence against pregnant women; the Mexico City policy, also known as the Global Gag Rule; surrogate maternity; and drug use and pregnancy. For example, the Unborn Victims of Violence Act, enacted in 2004, known as the “Laci and Conner Law,” establishes the same penalty for killing a fetus in utero as for killing a pregnant woman. Both sides in the abortion debate have seen this legislation as a step toward criminalizing abortion. The Mexico City policy forbids foreign nongovernmental organizations that are recipients of American population assistance from referring their patients for abortions or from engaging in political activity to legalize abortion in their countries.

Advances in technology have brought many new questions, including who should pay for in vitro fertilization, who is able to benefit from this technology, whether children conceived with donated sperm or ova have the right to know their biological origins, and whether embryos can be created for research purposes. In human reproduction, science has raced far ahead of policy. All of these issues and many more will be decided within the rubric of reproductive politics.

Since Roe v. Wade, the coalitions in this policy arena have been fairly consistent, and they have become more partisan. Pro-choice groups tend to line up with other groups supporting access to contraception and comprehensive sex education. Pro-life groups tend to support abstinence-only education as well as legally mandated parental involvement in both contraceptive and abortion decisions. Several prominent scholars think that these divisions are based on beliefs about the role of women. Although there are individual exceptions, the Democratic Party generally reflects the pro-choice positions, and the Republican Party espouses the pro-life position. Advances in reproductive technology, however, sometimes alter these coalitions; the stem cell controversy within the Republican Party is an example of such a development.

REPRODUCTIVE POLICIES OUTSIDE THE UNITED STATES
Although American reproductive politics are particularly contentious, public debates about reproductive issues are certainly not confined to the United States. Issues that achieve prominence vary by region and culture. In western Europe, for example, adolescent sexual activity is generally a subject for public debate. Public health policies support widespread contraceptive availability. Consequently, western European abortion rates are a small fraction of those in the United States. Moreover, abortion politics are not as nearly as vociferous.

Low fertility is a concern in much of Europe and Japan. Public policies to increase childbearing have had mixed results. Generous French maternity leave and child-care policies, however, have apparently achieved their pro-natalist objectives, and recently the Japanese birth rate has increased slightly.

In much of the world, reducing fertility rates is still on the public agenda. China retains its one-child policy, instituted in 1979, although the impact of that measure on fertility has been debated. Moreover, the one-child policy has skewed the ratio of males to females in that nation. As birth rates decrease in Latin America, politics in that
region are focusing more upon maternal health measures such as legal access to emergency contraception and safe abortion.

As a continent, Africa has the highest fertility rates in the world as well as some of the highest maternal mortality ratios due to the unavailability of contraception, female genital mutilation, and unsafe abortion. Because of the low status of women in many African countries, these issues have not been salient until the mid-2000s. The HIV/AIDS epidemic has put reproductive politics on the public agenda in several African nations.

REPRODUCTIVE RIGHTS
Reproductive rights is a term used to describe the rights of individuals as it relates to sexual reproduction, including the right to have or not have children; to have information about all aspects of sex, sexuality, and reproduction; to have the highest attainable level of reproductive health; and to be free from harassment, coercion, and violence with respect to sex and sexual expression. Reproductive rights encompasses concepts of both privacy (the right to decide on matters related to reproduction and sexuality without intervention by other individuals, institutions, or governments) and human rights, which are founded on principles of dignity and equality for all people. Because women are uniquely affected by matters relating to reproduction (including pregnancy, childbirth, and in most societies, childrearing), many people view women’s rights as inextricably tied to reproductive rights. As a result, women have historically led and been the focus of many of the struggles for reproductive rights around the world. These movements have included efforts to gain access to contraception; legalize abortion; reduce maternal mortality; give birth without unnecessary medical intervention; have sexual pleasure and health; and eliminate rape and sexual harassment, to name just some.

EXAMPLES OF DENIAL OF REPRODUCTIVE RIGHTS
There are many examples of the denial of reproductive rights in the United States and around the world. One example is the experience that many women have had with forced sterilization. In the United States, permanent sterilization of women who were deemed socially “unfit” to have children either because of their race, socio-economic status, intelligence or mental stability (or some combination of the above) became a common practice as early as 1907 in many states. The United States also carried out similar policies in Puerto Rico beginning as early as 1898 when it took over governance of that country. Thus, many women, particularly those who were poor, of color, uneducated, or mentally retarded were sterilized either without their consent or against their will. This form of abuse went on into the 1970s when a movement to end sterilization abuse eventually led to laws and regulations that ended this practice.

Other examples of reproductive rights abuses (both historic and current) include rape as a weapon of war; forced childbearing (as evidenced by laws restricting access to contraception and abortion); female genital circumcision; and a lack of control over childbirth practices (as evidenced by high rates of cesarean section or conversely lack of access to emergency obstetric care). Many other examples of reproductive rights abuse exist.

HISTORY OF REPRODUCTIVE RIGHTS MOVEMENTS
Although humans have attempted to control their reproductive destinies for many thousands of years, the notion of “reproductive rights” is a relatively recent phenomenon. The term was first articulated on a global level in 1984 at the International Meeting on Women and Health in Amsterdam. However, in individual societies and countries around the world, movements to gain rights related to reproduction had emerged prior to this time. Nonetheless, these movements were discrete and in many cases, such as with the struggles to legalize contraception and abortion in the United States, the focus was primarily on rights as they related to an individual’s right to privacy. It was not until the meeting in Amsterdam that the
emerging concept of human rights was applied to reproductive concerns, marking the beginning of what would become a global "reproductive rights" movement.

Following the 1984 meeting, the next significant international gathering in which reproductive rights became a major focus was at the World Conference on Human Rights, held in Vienna in 1993. At the Vienna meeting, participating countries agreed that any violation of the specific rights of women would be regarded as a human rights violation. Furthermore, an important shift in human rights theory took place at that meeting with the groundbreaking recognition that human rights exist in both private and public realms and as such, can be violated in either sphere. This shift brought the notions of privacy and human rights together, a critical joining of two previously separate ideas at an international level, which further spurred the global reproductive rights movement.

Since 1993 there have been a number of other significant international meetings that have built upon the foundations that were established in Amsterdam and Vienna to promote an international reproductive rights agenda and movement. In 1994 the United Nations International Conference on Population and Development (ICPD) in Cairo codified and furthered these ideas through its consensus document, the ICPD Programme of Action which states:

Reproductive rights embrace certain human rights that are already recognized in national laws, international human rights documents and other consensus documents. The rights rest on the basic right of all couples and individuals to decide freely and responsibly the number, spacing and timing of their children and to have the information and means to do so, and the right to attain the highest standard of sexual and reproductive health. It also includes the right to make decisions concerning reproduction free of discrimination, coercion and violence, as expressed in human rights documents. (ICPD 1994, paragraph 7.3)

Similarly, the United Nations Fourth World Conference on Women held in Beijing in 1995 advanced a broad agenda that linked women’s advancement and empowerment globally to human rights, and recognized reproductive rights as a critical element to achieving the goals it laid out as part of its future agenda.

Since those seminal meetings, there have been numerous follow up gatherings at international and regional levels where reproductive rights advocates from both government agencies and non-governmental organizations have come together to assess progress and further implementation efforts related to these goals, formidable challenges unto themselves. These efforts have been further complicated by the influences of a growing, worldwide movement to restrict reproductive rights—in particular abortion, but also contraception and freedom of sexual expression. This movement is based in conservative beliefs and/or religious fundamentalism. The United States has been extremely influential in this regard, using its significant power to block the passage of consensus documents that aim to promote a broad reproductive rights agenda from these meetings and refusing to provide funding to reproductive health organizations in other countries that have any connection to abortion procedures. These actions have had a chilling effect on efforts to advance reproductive rights around the world.

At the same time that these anti-abortion and anti-sexuality movements have emerged in the United States and other parts of the world, reproductive rights advocates have also expressed concern about practices that lead to the selective termination of fetuses and coercive abortions. For example, in India the use of ultrasound or amniocentesis to determine the sex of a fetus has been a growing practice that has led to an increase in the rate of abortion of females. In China, the government mandated one-child policy has led to a high rate of abortion which may often not coincide with a woman’s choice. Both of these examples represent reproductive rights violations from another angle.

In the early twenty-first century a dialogue emerged within reproductive rights movements in the United States (and elsewhere) about the need to expand to a broader concept of “reproductive justice” in order for women and girls to truly achieve “complete physical, mental, spiritual, political, economic, and social well-being” (ACRJ 2005, p. 1). Critical of the traditionally narrow focus on individual women’s rights and the reliance on primarily legal or public policy strategies that many reproductive rights groups have relied on, those who advocate a reproductive justice framework emphasize the need to promote “a model grounded in organizing women and girls to change structural power inequalities” (ACRJ 2005, p. 2).

With the advent of new reproductive technologies (such as assisted reproductive technologies, cloning, and genetic screening), a growing global population, and widening health disparities in the United States and around the world, struggles for reproductive rights will undoubtedly continue to be a dynamic and compelling aspect of human society into the foreseeable future.

REPUBLIC

The origin of the term republic lies in the Latin phrase res publica, or “public thing.” The term implies the development of the public, distinct from the private, in both degree and manner. First, a republic must be developed socially and economically to a degree that sets it apart from a mere collection of private households. Second, a republic must be developed politically in a manner that distinguishes its rule from despotism, wherein the ruler regards all land and people as his or her private property. Over time, as noted in Paul Rahe’s definitive work, Republics Ancient and Modern, republics have taken on different characteristics. Some have been authoritarian, using the power of the regime to establish a fixed way of life for all citizens, while others have been liberal, allowing citizens to pursue happiness as each individual defines it. Over time, the idea of religious toleration left decisions about faith to individuals, prompting the secularization of the modern republic. With greater emphasis on the household, there was less justification for the use of law to establish a common way of life. This did not, however, constitute an unqualified preference for the private, or any disregard for the public. Rather, the expanded private sphere was intended to serve a public purpose by mediating and channeling behavior driven by self-interest to raise the standard of living for all.

Thus, the modern republic is, by definition, liberal in character, existing not for virtue but for security. Consequently, modern republics feature institutional safeguards to prevent the abuse of power, particularly the separation of the legislative, executive, and judicial branches, as recommended by the French philosopher Montesquieu. Most scholars, including Thomas Pangle, credit Montesquieu and Locke with having a considerable influence on the founding of the United States. Others, however, such as J. G. A. Pocock, dispute the degree of this influence.

James Madison took a special interest in the development of republics, noting the problem of instability that had plagued both classical and modern regimes. In Federalist No. 10, Madison argued that instability was the result of factions, or organized groups motivated by a common goal adverse to the rights of others. Factions arose because republics permitted citizens to formulate individual opinions, gave them the freedom to associate, and offered groups the ability to influence policy to reflect their narrow interests. Madison’s solution was the extensive commercial republic, which was a break with earlier thinkers who believed republics had to be small and homogeneous.

Madison used the idea of representation to distinguish the republic from a pure democracy. A representative government, he argued, could take in greater territory and population. People would put the land to use differently, and the different types and amounts of property

would lead to diverse opinions. This would result in a multiplicity of factions, such that no single interest could dominate political decisions—a condition Robert Dahl famously termed pluralism. However, James W. Ceaser, among others, has disputed the fidelity of Dahl’s logic to Madison’s argument. Madison’s strategy intended the political arena to be a public place where people of differing passions and interests would engage one another, allowing the experience to refine and enlarge their views. This would produce decisions that did not benefit some at the expense of others, but that were conducive to a common good. Ultimately, Madison’s plan would have a centralizing effect on public opinion, but it would still offer freedom for those who desired to pursue more unconventional ideas.

Pressure from those exercising the right to explore the margins continues to redefine the center. This has made the modern republic the site of important rights movements, particularly the women’s liberation movement and the civil rights movement. This has intensified as globalization has prompted yet another reconsideration of the place of the market, religion, and the household. Economically, some want the market to be more purely private, seeking to reduce regulatory controls on land use, production, and exchange. Others advocate greater public control over the marketplace in the name of safety, fairness, and increased public assistance to the poor. At the same time, some desire a greater separation between religion and the public sphere, while others would prefer to see an increased public role for religion, allowing church groups to replace government agencies in the provision of social services. Finally, there is a debate over the nature of the household itself. Many republics, for example, are considering public recognition of same-sex marriages. Some see these changes as the next logical step in the evolution of the republic. Others consider them a radical departure and a threat to the very existence of the republic. Thus, the persistent redefinition of the relationship between public and private, especially with regard to the economy, religion, and the household, continues to shape the nature of the republic.

REPUBLICAN PARTY

The Republican Party is one of the two major parties in American politics and government. Like the Democratic Party, the Republican Party’s organization reflects federalism and the separation of powers. Each state has a Republican state committee and most American cities, towns, and counties also have Republican committees. Usually, Republican voters choose members, officers, and chairs of these state and local committees. Through primaries and caucuses, they also choose delegates to represent them at Republican national conventions.

Republicans in the states and territories also choose members of the Republican National Committee (RNC). In addition to representing their states and territories in the RNC, RNC members also elect RNC officials, such as chairs and treasurers, who choose the city that will host the next Republican national convention, and determine party rules and procedures, relating to such matters as the apportionment and selection of delegates from the states and territories and platform-making processes. At Republican national conventions, held during the summers of presidential election years, the major responsibilities of Republican delegates are to ratify or reject national platforms and to nominate presidential and vice presidential candidates.
Besides federalism, the separation of powers also divides and distributes the Republican Party's organization, authority, and functions. The National Republican Congressional Committee (NRCC) and the National Republican Senatorial Committee (NRSC) respectively serve the campaign needs of Republican candidates who run for election or reelection to the U.S. House of Representatives and Senate. Like the RNC, the NRCC and NRSC receive and distribute campaign funds and provide research, information, and literature on Republican policy positions, media and mailing services, and coordination among Republican candidates. The campaign finance role of the RNC, NRCC, and NRSC has diminished as Republican presidential and congressional candidates have become more dependent on individuals, state and local party committees, and interest groups, such as the National Rifle Association (NRA) and Christian Coalition, for campaign spending and the delivery of campaign services, such as advertising, direct mail, and voter mobilization.

The Republican Party was established in 1854. Most of its founders were disaffected Democrats and former Whigs. The Republican Party's major, initial policy position was its opposition to the extension of slavery into new states and territories. It adopted this policy position from the Free Soil Party, which it soon absorbed. Like the Whig and Federalist parties that preceded it in the two-party system, the Republican Party supported high, protective tariffs, a national bank, federal supremacy over the states, and a flexible interpretation of the federal government's powers in the Constitution. With the Democratic Party divided over the slavery issue, Abraham Lincoln was elected as the first Republican president in 1860.

During the period of closely contested presidential elections from 1876 until 1896, Thomas Nast, a political cartoonist, popularized the use of the elephant as the unofficial symbol of the Republican Party, which was also nicknamed the “Grand Old Party,” or the GOP, because of the party's close association with the Grand Army of the Republic, an organization of Union army veterans of the Civil War. In 1896 the Democratic Party nominated William Jennings Bryan for president. Bryan was a Nebraska congressman affiliated with both the Democratic and Populist parties. His rousing campaign speeches zealously denounced the GOP's positions on high tariffs and the gold standard for enriching big business and impoverishing farmers and laborers.

Orchestrated by Marcus Hanna, an Ohio businessman, the Republican presidential campaign portrayed Bryan as a dangerous economic radical and rural demagogue with an anti-urban, anti-immigrant bias and contended that high tariffs and the gold standard promoted a broad, national prosperity. The Republican landslide in the 1896 national elections established a long-term Republican realignment of voters that enabled the GOP to usually control the presidency and Congress from 1896 until 1932. Growing intra-party conflicts between the Old Guard, i.e., the conservative wing, and the Progressives, i.e., the GOP's liberal wing, helped Woodrow Wilson, a Democrat, to win the 1912 and 1916 presidential elections.

The Great Depression that began in 1929 during the Republican presidency of Herbert Hoover discredited the Republican Party's reputation among many Americans for competent economic leadership and ended their association with national prosperity. Democratic president Franklin D. Roosevelt's attractive leadership style and the popularity of New Deal economic policies broadened and diversified the coalition of the Democratic Party, thereby transforming it into the new majority party among voters. In particular, African Americans, who recently were the most loyal Republican voters, became the most loyal Democratic voters during the 1930s because of Roosevelt and the New Deal, despite the continuing association of the Democratic Party with Southern whites and segregation.

The Democratic realignment of the 1930s helped the Democratic Party to dominate American politics and government until the election of Republican president Richard M. Nixon in 1968. During those years, Republicans disagreed about how to defeat Democrats in elections and what ideological and policy alternatives they should offer American voters. Moderate and liberal Republicans, such as President Dwight D. Eisenhower (1953–1961), accepted most of the New Deal's policy legacy and an internationalistic, bipartisan foreign policy in the cold war. These Republicans emphasized that the GOP could manage liberal Democratic policies with greater efficiency and fiscal responsibility and could achieve civil rights for African Americans more sincerely and effectively than the Democratic Party, with its powerful anti-civil rights Southern wing in Congress. Meanwhile, conservative Republicans, such as Senators Robert A. Taft of Ohio and Barry Goldwater of Arizona, criticized the moderate-liberal wing of the GOP for “me too-ism” and argued that the GOP would perform better in federal elections if it offered voters a distinctly conservative ideological and policy alternative to liberal Democratic policies and candidates. This conservatism included an emphasis on less domestic spending, greater protection of states' rights and property rights through opposition to new civil rights bills, and a more nationalistic, aggressive, and partisan American foreign policy in the Cold War. Nonetheless, except for the 1964 presidential election, moderate and liberal Republicans dominated the GOP's presidential nominations and major platform
planks at Republican national conventions from 1940 until 1980.

Despite the Democratic realignment of the 1930s, a substantial minority of African Americans remained Republicans because they perceived the Republican Party, with its “Lincoln legacy,” to be more sincere and effective on civil rights. To black Republicans, the noisy defection of some Southern Democrats to Strom Thurmond’s “Dixicrat” presidential candidacy in 1948, because of their opposition to Truman’s doomed civil rights legislation, proved that the Democratic Party would also be sharply divided between its Northern and Southern wings on civil rights. In the 1964 presidential election, however, Barry Goldwater, one of the few Republican senators to vote against the Civil Rights Act of 1964, received most of the Southern white vote and only around 6 percent of the black vote. As the presence and influence of conservative Southern whites steadily increased within the Republican Party, fewer white Republican politicians supported liberal policies on race, such as affirmative action, court-ordered busing, and antipoverty programs.

During the 1970s, conservative Republicans, such as Ronald W. Reagan, often disagreed with the moderate policies of Republican presidents Richard M. Nixon and Gerald R. Ford, especially regarding détente with the Soviet Union and China. After nearly defeating Ford for the GOP’s 1976 presidential nomination, Reagan was nominated and elected president in 1980. Reagan’s policy goals prioritized the conservative agenda of major tax cuts, defense spending increases, reduced federal regulation of the economy, less domestic spending, a return of more domestic policy responsibilities to the states, and a more aggressive foreign policy. Aided by Republican control of the Senate from 1981 to 1987, Reagan increased the number of conservative federal judges, especially those with conservative judicial positions on abortion, crime control, school prayer, and other social issues. The conservative domination of the GOP by the end of Reagan’s presidency (1981–1989) was also a consequence of the growing political influence of the religious right, especially in the South.

Although William J. Clinton, the Democratic presidential nominee, won the 1992 presidential election against Republican incumbent George H. W. Bush, the Republicans won control of both houses of Congress in 1994. For the first time since the Reconstruction Era (1865–1877), most members of Congress from the South were Republicans. When Republicans in Congress impeached Clinton and tried unsuccessfully to convict him during 1998 and 1999, polls indicated that many Americans perceived the Republican leadership of Congress, especially Speaker of the House Newt Gingrich, to be harsh, extreme, and unreasonable in its relationship with the president.

Realizing the need for the GOP to express a more inclusive and less divisive type of conservatism, George W. Bush, the Republican presidential nominee in 2000, promised an ideology and domestic policy agenda based on “compassionate conservatism” during his successful presidential campaign. Bush’s “compassionate conservatism” included cultivation of minority voters, especially Latinos, and his proposal to use “faith-based initiatives” to provide some federally funded social services. Following the terrorist attacks of September 11, 2001, Bush’s perspectives, actions, and objectives in foreign and defense policy were influenced by neoconservative positions. Neoconservatism advocates and justifies the use of American military force, including preemptive attacks and invasions, to protect the security of the United States and its allies, especially Israel, and to promote freedom and democracy in the Middle East. Neoconservatives are willing to engage in these actions, including “nation-building” efforts in American-occupied Afghanistan and Iraq, without the support and participation of most U.S. allies.

After Bush was reelected in 2004 with 44 percent of the Latino vote and a victory margin of over three million popular votes, Karl Rove, Bush’s top political strategist, hoped that Bush’s presidency would stimulate a Republican realignment of voters similar to that of 1896. As Bush’s second term progressed, however, the president experienced low public approval ratings, and more Republicans in Congress openly disagreed with each other and Bush over the Iraq war, deficit spending, and immigration. The Democrats won control of Congress in the 2006 elections with net gains of twenty-nine House seats and six Senate seats. Polls and media analyses indicated that voters were reacting against lobbying scandals, the Iraq war, inadequate health care, and Republican control of both the presidency and Congress.

REPUBLICANISM

In rudimentary form, the origins of republicanism can be traced to Aristotle (384–322 BCE). However, this political form finds its first institutional embodiment in the republic of Rome (510–23 BCE), and its most comprehensive expression is in the writings of Marcus Tullius Cicero (106–43 BCE) and Titus Livius (59 BCE–17 CE). Both Cicero and Livius argued that Rome’s failure resulted from internal corruption and conflict, which disrupted the checks and balances between the senate, the magistrates, and the people. The tradition was amended and revived during the Middle Ages and the Renaissance by Italian city-states and thinkers such as Niccolò Machiavelli (1469–1527) and Francesco Guicciardini (1483–1540). It underwent further developments in England and the United States in the seventeenth and eighteenth centuries, when individuals such as James Harrington (1611–1677), Thomas Jefferson (1743–1826), and James Madison (1751–1836) attempted to restrain or remove monarchical power.

Republicanism is a political doctrine principally concerned with freedom and its realization through self-governance. For republicans, the people are the source of sovereignty. Freedom thus consists in not being subject to another’s will, and by having the power to raise claims for or against the laws under which one is governed. The primary danger to freedom, republicans argue, comes in the form of internal corruption and conflict that, if left unchecked, threaten to run roughshod over the common good. In its classical form, it emphasizes the importance of a mixed constitution that provides an institutional balance between the diverging interests of the many (the plebeian or democratic element), the few (the patrician or aristocratic dimension), and the one (the monarchical aspect) in society. The classical model is reflected in the Roman system, which included tribunes of the people, the aristocratic Senate, and consuls, usually two elected annually.

Classical republicanism, however, has undergone an important transformation in modern times, centering on the weight different thinkers attach to self-governance. Robert Dahl refers to this as a shift in emphasis from the older aristocratic republicanism to a radical view that places a greater emphasis on the democratic character of the constitution. The older aristocratic position is articulated by thinkers such as Aristotle and Guicciardini, while the second radical character is embodied in the works of Machiavelli, Paine, and Jefferson.

While both forms worry about the consolidation of power and the extent to which it will become a form of domination, they disagree over how this danger will be realized, and from what sectors of society. In the older view, the people have an institutional place in the constitutional structure, but because they lack the reflective capacity to curb their desires, the constitution needs to limit their power to selecting leaders that will govern on their behalf. Aristocratic republicans argue that these individuals are guided by an interest in the public good and have an ability to engage in impartial and careful reflection, making them uniquely situated to govern on the people’s behalf and for their long-term interests.

In contrast, egalitarian republicans believe that modern societies no longer reflect these distinct social classes. The presence of a hereditary aristocracy, for example, becomes increasingly difficult to distinguish, especially in the earlier American context. Egalitarian republicans further argue that those trying to balance the aristocratic and democratic elements of society fail to see that the only legitimate good is the public good. The hallmark of modern republican transformation, then, consists in dividing powers among separate institutions more carefully than reflected in the mixed constitution, with each serving as a check on the other. Modern examples include the British parliamentary system, and the United States Constitution, with its executive branch, bicameral legislative branch (the House and Senate), and judicial branch. The significant improvement to note is that these different branches of government do not reflect diverging but natural political cleavages in society vying for supremacy. Rather, they are constructed institutional appendages in which each element is but a part, with each designed to realize and protect the public good. As such, the public good is no longer a by-product of an institutional arrangement, as was often the case in the older view, but rather the end to which those institutions aim.

Another important transformation relates to political representation. Classical republics were unable to effectively incorporate growing populations into their institutional structure to ensure that the people remained sufficiently involved. In the case of Rome, for example, a population expansion did not result in a further development of sites for political participation. The problem of participation in large republics seemed pointed to a limitation of the political doctrine—namely, that it was inappropriate in the modern expansive nation-states of the seventeenth and eighteenth centuries.

In modern times the answer comes in the form of representative democracy. As John Locke (1632–1704), Baron de Montesquieu (1689–1755), and Madison argue, a modern republic can connect the otherwise antidemocratic practice of representation with the sovereignty of the people. Indeed, as Madison explains in Federalist No. 39, the people never give up their power because they always hold in reserve the right to change their representatives. Representation is based upon a revocable trust precisely because it is merely a proxy for direct participation and not a replacement of popular sovereignty. The result
allows power to extend over vast territories in response to various problems of collective organization.

RESEARCH, CROSS-SECTIONAL

A cross-sectional study is a type of research study widely used in economic, social, health, and marketing research. A cross-sectional study provides a snapshot of the distribution of factors and outcomes in a population at a specified period of time. In this type of study the prevalence of specific factors and outcomes can be calculated for a given population (community, state) and levels of exposure to factors and outcome status can be compared. In contrast to other study designs, cross-sectional studies sample individuals not based on their outcome status or the presence of a particular risk factor; rather, the presence of factors and outcomes are determined simultaneously.

Cross-sectional studies are very useful from the policy and public health point of view because, for example, they can provide a picture of the burden of a particular disease in a population and measure the prevalence of risk factors, such as smoking, in the population. However, this type of study is limited in its ability to give rise to inferences about causality. Cross-sectional studies are also very useful in monitoring conditions in a population, such as the surveillance of specific diseases (e.g., diabetes) or important risk factors (e.g., obesity), or in monitoring socioeconomic characteristics of the population (e.g., unemployment).

Cross-sectional studies offer several advantages over other types of research design. Compared to longitudinal cohort studies, which are studies that follow individuals with and without a specific risk factor over time to observe the occurrence of outcomes, cross-sectional studies are cheaper and can be carried out faster. Cross-sectional studies also allow for examining multiple factors and multiple outcomes in one single study. Generally, cohort studies can evaluate only one risk factor at a time, and case-control studies, a type of study that selects participants based on their outcome status, can evaluate only one outcome at a time. Another strength of cross-sectional studies is that when they are based on a representative sample of the population, their results can be generalized to the overall population from which the sample came. Analyses of surveys using representative samples require special analytic techniques to account for the sampling probability—the probability of being selected as a participant in the study—since this type of survey may oversample segments of the population (e.g., minority groups) to make sure they are adequately represented in the survey.

A major limitation of cross-sectional studies is called temporality bias. Since risk factors and outcomes are measured simultaneously, it is not possible to know whether the factor preceded the occurrence of the outcome, which is a criterion for determining causality. For example, in a cross-sectional study relating unemployment to heart disease, we cannot determine whether being unemployed contributed to the development of disease, or whether heart disease caused people to lose their jobs, perhaps by making them too sick to continue working. Another limitation that is particularly important in medical research is that in cross-sectional studies, diseases with longer duration are overrepresented because people who have the disease for a longer period are more likely to be included in the sample compared to people who quickly recovered or died from it. Thus, the association observed between risk factors and the disease may reflect survival rather than etiology. This limitation is often referred to as length bias or prevalent case bias.

Opinion polls are cross-sectional studies. They are commonly used in political research to determine voters’ preferences for candidates in an election, people’s perceptions of government policies, and the distribution of these preferences and perceptions by segments of the population such as gender, race/ethnicity, and age group. In mar-
In the education field, cross-sectional studies are used to examine factors associated with academic achievement. For example, Gwen Glew conducted a survey of elementary schools across the United States that reported a high prevalence of bullying and found that bully victims have low academic achievement and feel unsafe at school. Cross-sectional studies are widely used in medical research to identify risk factors associated with disease and explore associations among risk factors, as well as factors associated with health care. These studies have helped to identify the risk factors for heart disease (smoking, hypertension, cholesterol), determine the association of psychosocial factors (e.g., self-efficacy) and dietary behaviors or physical activity, and examine ethnic and gender inequalities in access to health care (e.g., access to cardiovascular procedures).

An example of the use of cross-sectional studies in surveillance is the National Health and Nutrition Examination Survey (NHANES). In this national survey, a representative sample of the population living in the United States has a comprehensive examination and completes questionnaires about their lifestyle behaviors. Such a survey reports on access to health care, the prevalence of overweight and obesity, dietary patterns and physical activity levels across U.S. states, and other health-related factors. The NHANES is repeated periodically and allows researchers to compare trends in health behaviors and conditions over time. The Youth Risk Behavior Survey (YRBS) is another example of a national cross-sectional survey. The YRBS, a school-based survey of adolescents living in the United States, reports on the prevalence of lifestyle behaviors such as smoking, drug use, sexual behavior, fruit and vegetable intake, and physical activity levels.

**RESEARCH, DEMOCRACY**

Research into democratization is as old as the democratic idea. Aristotle studied, with some prejudice, the democracy of Athens. Much later, James Madison tried to design a “republican remedy” for the “disease” of too much democratization. For most of western history, democracy was mistrusted by most of those most famous for having studied it.

Democracy as a positive ideal had a rebirth in the nineteenth century, eventually attaining hegemony after World War II as the political ideal appropriate for all nations (even Communist nations such as East Germany—the German Democratic Republic—claimed to be democratic). Research into democratization therefore is perceived by many today to be research into the best possible form of political society.

**DEMOCRATIZATION RESEARCH TODAY**

What, however, are we researching when we research democratization? Most western political scientists have defined democracy in ways that mirror the political and legal institutions and political culture of western liberal states, including ideas about citizenship, constitutions and rights, market economy, and separation of the public and private spheres. In this, political scientists have moved the ideal of popular rule in a decidedly liberal, republican, and market-oriented direction.

This predilection was reinforced by a mid-twentieth-century turn in the study of politics away from political science, broadly conceived, toward a social science presumed to be modeled on the natural sciences. Many students believed that “operationalizable” standards with which to measure democratic performance could only be “scientifically” derived from existing democracies—that is,
from the west. Although this model is open to the charge of being culturally and ideologically biased, it contains important democratic features, and it is the one that has been most often used as the standard for democratization research.

In the 1960s modernization theory, premised on the developmental path of western industrial societies, took hold among western political scientists studying newly (re)emerging nations. Similarly, in the 1960s and 1970s some scholars sought to discover prerequisites for establishing stable democracies, mirroring modernization theory. As authoritarian regimes fell in the mid-1970s, democratization studies grew rapidly. By the 1980s, instead of developing a general theory of democratization, scholarship moved to trying to understand strategic interactions between elites, downplaying the importance of masses in democratic transitions, and to categorizing the forces at work in democratic transitions, the type of democratic political system being created, and the requirements for democratic consolidation. In the 1990s studies shifted to also trying to study democratic development over time. Scholars popularized the metaphor of three democratization “waves”: the first from 1826 to 1926; a shorter post–World War II wave; and the famous “third wave,” beginning around 1974. It is this third wave, encompassing developments in Latin America, Eastern Europe, and East Asia, that most democratization research explores.

Overall, the literature recognizes four stages in the transition to democracy: decay of authoritarianism, transition, consolidation, and maturation. Democratization is facilitated by a decline in legitimacy of authoritarian rule due to either an inability to solve problems or a shift in values. It is supported by the development of civil society, increasing education and income levels, external democratic pressures and/or support, the “snowball” effect of being within a democratizing region, and citizens valuing it as an intrinsic good rather than for economic or social performance. Many scholars now believe the reasons for democracy’s emergence are not the same as those for its consolidation or maturation, and they see ebb and flow and sideways movement rather than linear progress.

In addition to regime type and patterns of transition and consolidation, scholars devote attention to the impact of democratization on regime performance; the need for a “mature state” for democratization; the importance of external actors, whether they be states or nongovernmental organizations (NGOs), in trying to promote internal democratization; and the effect of democratization on citizen well-being. Some who see strategic interaction among elites as decisive argue that third-wave democracies are fragile because democratic elites are forced to bargain with nondemocratic elites, and are further constrained by undemocratic constitutions that protect privilege. Some fear that fragile democracies can be overloaded with citizen demands, making the development of competitive economies problematic, thereby undermining the regime. Others think robust citizen participation is essential in democracy, and see international constraints on domestic democracy emanating from the “world market” and its key institutions.

Although analysts empirically find democratic features within “third-wave” regimes, such as free elections, other critical features of these regimes are found by some to be problematic, especially inadequate civil rights and concentration of power in the executive. They use a variety of terms to define these problematic regimes, such as “illiberal,” “delegative,” “imperfect,” and “immature” democracies. Scholars have begun to rethink whether some of these “hybrid” regimes should be called democratic at all, and have coined terms such as “electoral,” “competitive,” or “contested authoritarianism” to indicate a notion of “enhanced authoritarianism” rather than “qualified democracy.” Some “third-wave” scholarship indicates that democracy emerges through a complex process that varies from country to country with few preconditions or causing factors. Scholars often emphasize elite interaction as decisive in the foundation and consolidation of democracy, but some also still point to the importance of mass mobilization for both.

**CRITICISM OF DEMOCRACY RESEARCH**

Democratization research has been criticized in a number of ways that are relevant for future twenty-first-century researchers. Some criticism points to the need to further refine concepts and measurements, or to the need to be more selective in developing new concepts, or to how the “wave” metaphor can be misleading; others point to biases in the research itself and the inadequacy of past approaches to a more rapidly “globalizing” world.

An important line of criticism is that the overall emphasis on terminology is confusing and obfuscates the fact that although third-wave democracies may be less effective, the kind of problems they face—such as inequalities of rights, institutional power imbalances, and failures of accountability—were, and to a degree still are, faced by first-wave democracies. Favoring “minimalist” procedural definitions rather than robust ones that stipulate deeper notions of political equality and social justice, therefore, runs the risks of repressing the history of conflict and struggle in western democracy and of evaluating newer democracies by a sanitized and static metric.

Some caution researchers against trying to implicate other states or NGOs into the process of democratization, recalling the difficulty of efforts to “transplant” democ-
racy, including through war, for example, in Vietnam and Iraq. Others temper this by suggesting that research into efforts to aid democratization can be successful if they are culturally sensitive and invoke a broader standard than western liberalism.

**DEMOCRACY AND GLOBALIZATION**

Internationalization of the world economy brings both economic development and new ideas, which can aid democratization. However, it can also promote greater inequality and/or foster constraints on the choices open to democratically elected officials, which generally impede it. Research shows that lessening inequality and insulating politics from inequalities do advance democratization and make de-democratization less likely. The sources of inequality, however, are shifting to include not just domestic, coercive control characteristic of industrial and agricultural production, but also transnational niches of elite control of finance, science, technology, information, and media, characteristic of postindustrialism and global neoliberalism. These international forces of economics, business, politics, culture, communication, migration, and ideas such as democracy bring religions, cultures, and subcultures into closer contact, possibly stirring popular movements of political action and resistance. The democratic idea may even take on unfamiliar forms. Although procedural definitions and certainly constitutional protections remain very important benchmarks in the study of democratization, in this context, how are we to judge what should count as critical democratic supplements to them?

Researchers should also ask: Have elected representatives within western liberal democracies ceded significant new power to unaccountable international markets, administrators, and elites, thereby diminishing the real impact of the voting power—the democracy—of their citizens? Does research therefore need to evaluate global as well as national, regional, religious, and cultural obstacles to democratization, obstacles applicable to all societies, including those in the west? If so, the freedom and ability of citizens to organize across borders and to engage in international political participation and agenda setting become important measures of democratization for all societies.

As economic and political integration, and resistance to it, proceed toward an uncertain future, as new groups emerge and define their rights, democratization research faces another powerful challenge. Just as democratic theory has needed to—and continues to need to—address the harms done to those left out in the consolidation of liberal institutions, systems of representation, and even concepts of normal citizenship, whether of race, gender, ethnicity, or economic standing, so too, does democratization research need to open itself even more to the unfamiliar on all these registers. None of this obliges researchers to cede valuable standards—quite the contrary. It asks them to go back to the root and engage the primary but difficult question: In today’s world, what advances popular rule and what stands against it?

**RESEARCH, ETHNOGRAPHIC**

The discipline variously called social anthropology, cultural anthropology, ethnology, or ethnography seeks to describe the entire range of distinctive cultures in the world, past and present, and to arrive at a general understanding of human society through systematic comparison between them. This vast research undertaking uses a wide range of methods, both quantitative and qualitative, and is buttressed by related disciplines, principally archeology, human paleontology, biological anthropology, sociology,
demography, history, and psychology. Although anthropologists, like other social scientists, commonly use and even collect censuses, surveys, written documents, and other sources of data, and analyze them with the help of statistical methods, their main claim to methodological distinctiveness is fieldwork.

Ethnographic fieldwork consists of spending extended periods of time, ideally a year or longer, in intensive observation of, and interaction with, a study population. Such observations and interactions are recorded in the form of daily field notes, transcriptions of texts, construction of genealogies, and household surveys, often with the help of such mechanical devices as tape recorders, cameras, and camcorders.

Much of that methodology is shared with students of the behavior of other animals, namely ethologists or animal behaviorists, with, however, two crucial distinctions. Anthropologists and their study animal belong to the same species, and they communicate through symbolic language. This means that ethnographic fieldwork requires additional skills besides keen observation and recording. Though anthropologists sometimes work through interpreters, or use a common second language (such as Spanish in Latin America or French in Africa), being fluent in the language of a study population is considered important if not crucial to good ethnography.

The heart of fieldwork consists of the twin methods of “depth interviewing” and “participant observation.” Depth interviewing generally involves a small number of informants (five to twenty is a typical range), who are interviewed repeatedly and at length, preferably in their own language and over a period of months or even years. These informants are carefully chosen for their knowledge and understanding of their culture, and often become real partners in inquiry to the anthropologist. Participant observation consists of participation by ethnographers in the events they record and a general immersion in a culture, as opposed to simply observing and recording interaction from the outside. Ethnographers strive to be accepted, as much as possible, as one of those studied. In practice, however, total acceptance is rare, and total participation is not necessarily desirable. Ethnographers must be wary, for instance, of sexual involvement, of entanglement in local politics and factions, and of activities that may be illegal.

In the first half of the twentieth century, when it was first established, field ethnography was applied mostly to non-Western, non-literate societies, often colonial dependencies of the imperial countries to which anthropologists belonged. This led to the more recent criticism of anthropology as the handmaiden of colonialism, exemplified by Edward Said’s *Orientalism* (1979), and various articles in collections edited by James Clifford and George Marcus, and by Dell Hymes. If you studied whites, it was said, you called your work *sociology*; if blacks, *anthropology*. Partly in response to this criticism (and partly as a result of decolonization during the second half of the twentieth century), anthropologists increasingly applied their field methods to the entire range of human societies, including their own. We now have a thriving urban anthropology of Western societies, which was indeed figured by the “Chicago school” of sociology in the 1920s.

Related to the charge of colonialism leveled at anthropology is the question of who “owns” a culture, and who can legitimately interpret it and present it to the world. Some critics argue that only native members can and may do so. Clearly, there are advantages to belonging to the culture under study (familiarity, access, linguistic fluency, depth of understanding), and many ethnographic “informants” no doubt deserve more recognition as coauthors than some anthropologists are willing to grant them. However, the advantages of being an insider are counterbalanced by drawbacks (lack of objectivity and distance, taking too much for granted, being captive of one’s position within the culture). Ideally, perhaps, fieldwork should be done by a team consisting of insiders and outsiders.

Participant observation also raises several problems, which potentially affect the validity and reliability of ethnography. The first is the effect of the observer on the observed. Animal behaviorists speak of “habituating” their subjects, that is, of accustoming them to their presence, to the point that they are ignored. This is easy enough if one studies, say, ants, but much less so with chimpanzees. Between humans, true habituation is simply impossible, except in highly impersonal urban situations, where fieldwork can be done surreptitiously. But, then, fieldwork without the informed consent of those observed is generally considered unethical by most anthropologists.

Informants almost invariably alter or manage their “presentation of self” to the anthropologist. Their account of themselves and their people is contaminated by their personal interests, their likes and dislikes, their attempt to manipulate the fieldworker, and their perception of what the anthropologist likes or wants to hear. Not uncommonly, key informants become quasi-anthropologists, and adopt the approach of the fieldworker. Some are not above telling tall tales and pulling the anthropologist’s leg.

Another serious problem in participant observation is the inevitable tension between objectivity and subjectivity, between trying to be both an insider and an outsider. On the one hand, anthropologists seek a deep understanding of what an event, a ritual, a text, a conflict, a folktale means to their subjects. Ethnography involves telling the story from the native perspective, as an insider sees it. But it is not simply a matter of accepting at face value, then repeating, what informants have said. Understanding
social reality involves analysis, and that, in turn, implies detachment, seeing things as an outsider. The anthropologist is, thus, constantly involved in alternating between immersion in, and detachment from, the studied “reality.” Few anthropologists are naïve enough to claim Olympian detachment from “their people.” Indeed, most claim warm affection for them. But quite a few clearly disliked them. For instance, the great pioneer of fieldwork, the Polish-British anthropologist Bronislaw Malinowski, referred to the Trobrianders he made famous as “niggers” in his intimate diary. Others, like Colin Turnbull, make no effort to hide their likes (of the Mbuti) and dislikes (of the Ik). It is considered good form to address the problem of objectivity in ethnographic fieldwork through an explicit statement of one’s position and an account of one’s field experiences. Often such matters are relegated to a methodological appendix, but sometimes their explanation results in book-length autobiographies, such as those written by Claude Lévi-Strauss and Elenore Smith Bowen.

Finally, there is the issue of self-censorship. Many anthropologists refrain, for a variety of reasons, from telling all. They have a responsibility as scientists to share their findings, but they must also do their best to protect the anonymity of their hosts, to respect the secrets they pledged to keep, and to shield their hosts from condemnation, exploitation, or persecution by hostile outside forces.

In the 2000s, ethnographic research came under fire from academics of “postmodernist” persuasion, who have argued that objectivity is a delusion, that no human experience can truly be communicated, and that any attempt to do so is but one “discourse,” usually self-serving, among many. Such a position is one of intellectual nihilism: It negates the possibility of any social science. Understanding across cultural, gender, age, and class divides—indeed, between two persons of any kind—becomes impossible if everyone is enclosed within the self.

Others draw a different conclusion about ethnography, namely that from it emerges a vision of a common humanity, transcending the wide range of cultural differences and the diversity of anthropological approaches. From this perspective, the ultimate mission of anthropology is to make human diversity communicable, and, by doing so, to reveal our unity as a species.

BIBLIOGRAPHY
causality. Only with longitudinal data can the criterion of temporal priority be established unambiguously. In cross-sectional data one can sometimes infer temporality, but often one must trust memory, which is very unreliable. (This criticism applies equally to what are sometimes called longitudinal designs but which collect data retrospectively. The recall of attitudes and opinions is so influenced by the current state of those variables as to make recall an exercise in creative imagination.) In addition, if the research purpose is to study "flows" (e.g., the number of people who move into or out of unemployment during a month) rather than "stocks" (e.g., the number of people unemployed on a given date), then longitudinal data are absolutely required. The study of flows employs a turnover table, as illustrated by Bernard Levenson’s 1978 article.

Although temporal priority can be established via a longitudinal study, without a true experiment involving randomization and manipulation of an independent variable, causality cannot be proved. Large-scale social experiments, however, such as the negative income tax experiments of the 1960s and 1970s, involve longitudinal data collection and hence partake of all the advantages and disadvantages of longitudinal studies.

SPECIAL ISSUES IN LONGITUDINAL STUDIES

When investigators analyze data from longitudinal studies in the aggregate, they seek to separate age effects (caused, for example, by physical aging or moving to different age-related roles) from period effects (caused, for example, by changing social environments) and from cohort effects (caused, for example, by different social environments at critical stages in individuals’ development). Work by Erdman Palmore, as presented in his 1978 article, points out that longitudinal differences (between measurements of the same cohort taken at two time periods) are the sum of age and period effects; cross-sectional differences (between measurements of different cohorts taken at the same time period) are the sum of age and cohort effects; and time lag differences (between measurements of an older cohort taken at time one and those on a younger cohort taken at time two, when they have achieved the same age the older cohort was at time one) are the difference between period and cohort effects. Disentangling these effects requires careful thought and analysis, especially if only a single cohort is being followed over time.

Because measurements on the same unit at different time points are correlated, longitudinal data rely on special statistical techniques that take such correlation into account. Analogous to analysis of variance models appropriate for repeated measures designs, these techniques employ certain forms of generalized linear models. Dorothy D. Dunlop’s work from 1994 and that of James H. Ware from 1985 are explications of these statistical techniques.

The problem of attrition haunts longitudinal data collection. Researchers lose the opportunity to conduct follow-up when people move out of the study area, refuse to continue, or die. Investigators do their utmost to prevent attrition; for example, the PSID sends postcards to its respondents yearly to determine their whereabouts. Attrition degrades data from a longitudinal study to the extent that data from those not participating in later rounds differ from the data of those participating. Imputation of missing data is, in theory at least, easier for a longitudinal study than for a cross-sectional one, as data from earlier rounds of the study can aid in the effort; Roderick Little’s 1988 work offers examples of such techniques.

To avoid missing data, some longitudinal studies (e.g., NLSY) use a life-history method, asking respondents to report not only their current status on such variables as employment and marital status, but also to report and date any changes in these statuses since the previous interview. Thus if a respondent misses one or more interviews, longitudinal data for that respondent are nevertheless available from these retrospective reports, although possibly at some cost in accuracy if respondents’ memories are faulty.

When a longitudinal study is concerned with units other than individuals, additional complications arise. For example, PSID, which studies income dynamics for families, sampled approximately 4,800 families in 1968. Because PSID follows all members of these original families as they leave (children marrying, original couples divorcing, etc.), by 1996 the study encompassed about 8,500 families. To keep the sample representative of the general population, about 440 immigrant families were added in 1996 and almost 1,500 families had to be dropped.

When data are collected repeatedly from the same unit, those data present an increasingly detailed and thus increasingly identifiable picture of the study subjects. Thus issues of confidentiality and data security become increasingly important and increasingly difficult.

In addition to studies designed longitudinally to study change, several large-scale government surveys (e.g., the Current Population Survey [CPS] and the National Crime Victimization Survey [NCVS]) use rotating panel designs in which a unit participates in the survey for several reference periods. This design makes contacting respondents easier than if a new sample were drawn for every wave and increases the efficiency of statistical estimation. It is difficult for the government agencies collecting these data to link respondents across waves in order to
study them longitudinally; nevertheless, such linked files have been produced and used fruitfully in both methodological and substantive research.

RESEARCH, QUANTITATIVE
SEE Methods, Quantitative.

RESEARCH, SURVEY
Survey research is a methodological process by which social scientists convert theoretical concepts into numbers. The quantification of theoretical concepts via the survey instrument allows for the modeling of relationships between variables such as education and socioeconomic status. Surveys are used by researchers across all of the social sciences as one of the primary means of data collection. For example, in order to measure a theoretical concept such as religiosity, the social scientist can use an indicator or set of indicators of religiosity, and the aggregate responses can then be coded numerically. A common example of such an indicator is the question “How important is religion in your life?” The subjects being surveyed would typically select one of the following responses: “Very Important,” “Pretty Important,” or “Not Too Important.” The three response categories are then coded as follows: 1 = “Very Important,” 2 = “Pretty Important,” and 3 = “Not Too Important.” In this way, social scientists are able to quantify theoretical concepts.

EPISTEMOLOGICAL FOUNDATIONS
The philosophical underpinnings of survey research rest squarely on the side of positivism, as opposed to interpretivism. Positivist social scientists seek to emulate the level of quantification that is characteristic of the natural sciences, particularly physics. The aim of survey research, from a purely positivist viewpoint, is to discover the universal laws operating in society. It is thought that such laws are best uncovered through a deductive, scientific method, whereby data is collected through a survey instrument in order to test a theory. Interpretive theorists, with a more qualitative focus on issues such as meaning and historicity, are critical of positivist assumptions and tend to prefer a more inductive, theory-building approach to data collection.

QUESTIONNAIRE CONSTRUCTION
The successful execution of survey research depends in great measure on the proper construction of the questionnaire. Good questionnaires provide measures of theoretical concepts, also referred to as variables, that are concomitantly reliable (i.e., able to be reproduced) and valid (i.e., accurate). The questionnaire should be clear and concise in presentation and wording. The researcher can choose between single items or multiple items in order to measure a variable. For example, another question that measures religiosity might be: “How often do you attend religious services?” Possible response categories could include: 1 = “Often,” 2 = “Not Too Often,” and 3 = “Never.” This is an example of a closed-ended question, in which response categories are predetermined by the researcher. Such categories should be exhaustive (i.e., they should cover all possible responses) and mutually exclusive (i.e., there should be no overlap among the responses).

One of the most common sets of response categories is the Likert scale, which measures how strongly a person agrees or disagrees with a statement. One way to measure happiness, for example, is with a four-point Likert scale in
which the response categories range from “Strongly Agree” to “Strongly Disagree.” Consider the following indicator of happiness: “On the whole, I am happy with my life.” A standard Likert scale would code the responses as: 1= “Strongly Agree,” 2= “Agree,” 3= “Disagree,” and 4= “Strongly Disagree.”

When multiple items are used to measure a single concept like happiness, it is sometimes useful to invert some items, such as: “On the whole, I am unhappy with my life.” The inversion of items can disrupt potential patterns in which the respondent “Strongly Agrees” or “Agrees” with all of the items.

In addition to closed-ended questions, which tend to be comparatively high on reliability, survey instruments can also be constructed with open-ended questions, which tend to be comparatively high on validity. Open-ended items probe the respondent's knowledge on a given issue, but they do not offer a predetermined set of response categories. For example, a social scientist interested in studying the nature and determinants of trust might include the following item in a questionnaire: “What are the most important factors in your decision to extend trust?” The obvious advantage of such open-ended items is that the researcher does not need to be concerned with the development of exhaustive and mutually exclusive response categories. The major disadvantage is that open-ended responses, as a result of their variability, are difficult to code, leading to reduced reliability.

ADMINISTRATION AND INTERVIEWING

The three most common methods of administering questionnaires are by mail, by telephone, and in face-to-face interviews. Since the 1990s, there has also been an interest in the use of the Internet to administer electronic surveys. The principal advantage of administration via post and the Internet is the comparatively low cost of the research vis-à-vis telephone and personal interviews. The disadvantages of survey research conducted via post and the Internet are the comparatively lower response rates and the overall length of the research process.

Telephone interviews have the obvious advantage of being cheaper to conduct than face-to-face interviews. In terms of the length of the research process, a second clear advantage is that questionnaires can be administered and data collected more quickly than with face-to-face interviews. The third advantage of telephone interviews is that a random sample can be readily selected using random digit dialing (RDD), whereby a computer generates random telephone numbers. However, the fact that not every household has a telephone can bias the sample. Furthermore, telephone interviews are generally not suitable for long questionnaires.

The consensus is that face-to-face interviews yield the highest quality data. In general, there are three main advantages of face-to-face interviews. First, the instrument can be longer than if it were administered by telephone, post, or the Internet. Second, interviewers can use visual aids to assist respondents. Third, it is easier for interviewers to clarify questions and items that are unclear, although it is possible that clarification on the part of the interviewer can bias the results. The main disadvantage of personal interviews is the high cost involved in the research.

STRENGTHS AND WEAKNESSES

In short, survey research has several strengths vis-à-vis the more qualitative methodological approaches. First, the results of survey research are, on balance, more generalizable than the results of qualitative research. In other words, because of the greater number of respondents, survey research typically yields findings that are more representative of the population being studied. Second, survey instruments yield more reliable results than qualitative interviews. Third, questionnaires are useful in terms of both testing theories and establishing correlations between variables.

There are four main weaknesses of survey research. First, it can be potentially very expensive to conduct. Second, it is rigid and inflexible, especially in the absence of open-ended items. Third, it is open to the criticism of having a top-down bias; that is, it seldom allows for theory construction from the bottom-up. Fourth, although it is strong in terms of establishing statistical correlations, it is weak in terms of proving causality between two variables. In spite of these weaknesses, survey research is one of the most widely used methodological approaches.

Andrew R. Timming
identity to the related structures of inquiry of multidisciplinary and interdisciplin ary research.

The Transdisciplinary Prevention Research Centers defines trans-disciplinary research as "A cooperative effort by a team of investigators from diverse disciplines including meaningful representation of basic sciences as well as clinical or applied sciences. Normally, a trans-disciplinary team of investigators will include persons from different departments but the key issue is that the team will include members who bring markedly diverse methods and concepts to bear on the scientific theme" (Transdisciplinary Prevention Research Centers Request for Application, 2002).

To better understand trans-disciplinary research, one needs to distinguish its approach from other models. Multi-disciplinary and inter-disciplinary research are the two models that trans-disciplinary research broadens.

In his 2004 article "Transdisciplinarity and Its Challenges: The Case of Urban Studies" Thierry Ramadier distinguished the models this way: "Interdisciplinarity differs from multidisciplinarity in that it constructs a common model for the disciplines involved, based on a process of dialogue between disciplines" (Ramadier 2004, p. 433). In other words an inter-discipline is often a discipline of its own. Examples of this synthesis of disciplines are numerous and include such fields as biochemistry, social psychology, and biological anthropology. However a second important aspect of inter-disciplinary research lies in the practice of transferring models or tools from one discipline to another. For example, scholars might apply the mathematics of topography to the study of group dynamics. In this case, according to Ramadier, the concepts of one discipline are appropriated by the other disciplines. Ramadier maintained that interdisciplinarity, like multidisciplinarity, avoids paradoxes and having to solve them, resulting in fragmented approaches in each model.

He further argued that transdisciplinarity breaks away with this type of thinking in a significant way, since the objective is to preserve the different realities and to confront paradoxes between them. Transdisciplinarity is based on a controlled conflict generated by these paradoxes, and the goal is the search for more advanced articulation rather than consensus among the disciplines involved. Ultimately, through simultaneously combining multidisciplinary and interdisciplinary, transdisciplinarity transcends and incorporates these forms of thought. Ramadier argued that transdisciplinarity emerges from the confluence of the three scientific approaches of disciplinarity, multidisciplinarity, and interdisciplinarity.

In his 2004 article Roderick J. Lawrence describes multi-disciplinary research as:

Research in which each specialist remains within her/his discipline and contributes using disciplinary concepts and methods. Multidisciplinary contributions can be interpreted as the bringing together of disciplines which retain their own concepts and methods that are applied to a mutually agreed subject. In these studies one contributor will usually co-ordinate the research process and seek integration. Interdisciplinarity can be considered as the mixing together of disciplines, whereas transdisciplinarity implies a fusion of disciplinary knowledge with the know-how of lay-people that creates a new hybrid which is different from any specific constituent part. (Lawrence 2004, p. 488)

It is this “fusion” that distinguishes trans-disciplinary research from other research models. As with other models, team building is essential to success. Trans-disciplinary research, however, requires that traditional boundaries and responsibilities be set aside so that team members can fully embrace new skills and knowledge. It requires that team members be willing to step away from the prejudices of their individual disciplines and open themselves up to the perspectives of others, including lay-people, and embrace the learning that takes place when distinct ideas are threaded together. In their 1981 article Frederick Rossini and Alan Porter liken the trans-disciplinary process to a “seamless woven garment” in contrast to the “patch-work quilt” of multi-disciplinary research.

It is this holistic approach that proponents of transdisciplinary research find so rewarding. A trans-disciplinary research model accepts that complex problems are best understood by acknowledging, from the outset, that effective solutions are more than the sum of critical perspectives from a range of disciplines. It embraces a more modern approach that calls for true collaboration, a dynamic collaboration that crosses turf boundaries and insists that team members be responsible not only for their own success, but for the success of the team as a whole.

Trans-disciplinary research has found proponents in a wide range of research environments. The trans-disciplinary approach has been used successfully in areas as diverse as disability prevention, infectious diseases, drug misuse, and physical therapy. By examining these and other complex problems from a unique vantage point, trans-disciplinary research programs may offer a new perspective on solutions to serious problems, both old and new.

While it owes its origins to interdisciplinary and multidisciplinary research, the trans-disciplinary model has established itself as a distinct and modern research method. Basarab Nicolescu clarifies both the approach and goals of transdisciplinarity: "As the prefix 'trans' indicates, transdisciplinarity concerns that which is at once between the disciplines, across the different disciplines, and beyond all discipline. Its goal is the understanding of the present world, of which one of the imperatives is the unity of knowledge" (Nicolescu 2002, p. 44).

RESEARCH AND DEVELOPMENT
Research and development (R&D) is the term commonly used to describe the activities undertaken by firms and other entities such as individual entrepreneurs to create new or improved products and processes. The broadest meaning of the term covers activities from basic scientific research performed in universities and laboratories all the way to testing and refining products before commercial sale or use. The performance of, the incentives for, and the contributions of R&D are topics that are widely studied in management, economics, and other social science disciplines. Total spending on R&D activities is also one of the most widely used indicators of the innovative performance of firms, industries, and countries.

Informal R&D has existed at least since the first person experimented with methods of knapping flint to make Stone Age tools. In a formalized sense, it became part of the arsenal of the modern corporation beginning with the creation of industrial labs in the late nineteenth century, and in the early twenty-first century it comprises about 2 to 3 percent of the gross domestic product (GDP) in advanced economies. (For a history of the rise of organized R&D in the United States, see Mowery and Rosenberg 1989.) Spending on and outcomes of R&D investments have become important enough to be the subject of a satellite account in the U.S. System of National Income Accounts that was introduced in 2006 and 2007 (U.S. Department of Commerce 2006) and to be considered for inclusion in the international standard for systems of national income accounts (United Nations Statistics Division 2006).

The Frascati Manual of the Organisation for Economic Co-operation and Development (OECD), first published in 1963, created an international standard for surveys of spending on R&D. This manual defines R&D as “creative work undertaken on a systematic basis in order to increase the stock of knowledge, including knowledge of man, culture, and society, and the use of this stock of knowledge to devise new applications” (Organisation for Economic Co-operation and Development 2002, p. 30). R&D is generally thought to consist of three main activities: basic research, applied research, and development. Basic research is research undertaken primarily to acquire new knowledge without a view to its application. Applied research is research directed toward a specific objective, and development is work drawing on existing research results and is directed specifically toward the creation of new and improved products and processes. In general more than two-thirds of R&D spending by firms or countries is directed toward development rather than research. The 2003 OECD Science, Technology, and Industry Scoreboard reports that in developed countries with high R&D intensities, basic research is less than one-fifth of total R&D spending.

ECONOMIC ANALYSIS OF R&D
In the theoretical economics literature, the term R&D is commonly used to describe the conscious choice of firms and individuals to invest in the invention and commercialization of new products and processes. Although the activity described is seldom made precise in these models, in practice this kind of investment is assumed to correspond roughly to the spending on R&D that is reported in firm accounts and to various governmental surveys. Important insights into the motives underlying investments in R&D were first developed in seminal papers by Richard Nelson in 1959 and Kenneth Arrow in 1962. These two authors clearly argued the economic policy case for subsidies to R&D investment that arise from the nature of its output.

Briefly stated, the argument is that because most inventions (processes and products) can be imitated once they are made and at a cost lower than the original cost of making them, the incentives for undertaking R&D directed toward the creation of such inventions are inevitably weaker than society would like. The performance of R&D therefore generates positive externalities, or “spillovers,” that benefit others. Nelson distinguished between basic research with wide applications (which is most likely to be insufficiently provided) and development expenditures targeted to particular products or processes (which are more easily protected by patenting.
Research and Development

and other means). Arrow made the case for underinvestment in R&D more broadly by setting it in the context of the then newly invented Arrow-Debreu general equilibrium model. He argued that the allocation of resources for invention (that is, R&D spending) was likely to be nonoptimal because the production of information about new products and processes failed all three of the assumptions required for perfect competition to achieve a Pareto optimum: that the good (information) be infinitely divisible, that it be tradable on the market (that is, that its returns are fully appropriable by the owner), and that there be no associated uncertainty.

All three of these characteristics (indivisibility, inappropriability, and uncertainty) have proved to be important in the case of R&D. Indivisibility implies returns to scale because information about new products and processes can be spread over many units at increasingly lower cost per unit, leading to monopolistic competition in R&D-intensive industries. As Arrow and subsequent economic theorists have shown (see, for example, Reinganum 1989), this can lead to either over- or under-investment in R&D from a social perspective. In contrast, lack of full appropriability suggests that there will be underinvestment in R&D. In a 1992 article, Zvi Griliches surveyed the evidence on the existence of R&D spillovers, and based on the evidence on measured private and social returns to R&D from a wide number of empirical studies, he concluded that overall R&D spillovers were both “prevalent and important.” This result suggests that underinvestment dominates overinvestment, at least in the majority of sectors.

Finally, uncertainty about the nature of the information to be produced by R&D makes it a risky undertaking and sometimes implies that there will be an asymmetric information problem between its producers and those who might finance its production, again leading to potential underinvestment. Empirical evidence for the existence of difficulties in financing R&D investment is surveyed by Bronwyn H. Hall (2002).

R&D AS INVESTMENT

The term R&D is often followed by investment, which hints at one of its most important attributes. Research and development continues to benefit both those who undertake it and society at large into the uncertain future. Another attribute of R&D that has been emphasized in the modern economic growth literature is its cumulative nature, which can lead to increasing returns, both in the aggregate and also for individuals and firms. The idea is that the stock of knowledge created by doing R&D makes one more productive in acquiring additional knowledge. At the economy-wide level, this idea is the basis of the modern endogenous growth literature that is discussed in Philippe Aghion and Peter Howitt’s Endogenous Growth Theory (1998).

These attributes create some interesting problems for measurement and analysis. In general applied researchers have dealt with the intertemporal nature of R&D investment by treating it in the same way as ordinary investment in tangible assets, adding up expenditures to create an R&D stock and using a suitable depreciation rate to capture the fact that older research may become less useful over time. However, the aforementioned spillover effects make this exercise somewhat more speculative than in the case of ordinary assets, because R&D that has ceased to be useful for the production of private profit may still be useful to others in the production of new knowledge. The process that renders some R&D output obsolete is the same one that was termed “creative destruction” long ago by Joseph Schumpeter (1942). For a survey of the R&D depreciation problem and its implications for measuring the returns to R&D, see Hall (2006).

RESEGREGATION OF SCHOOLS

In Brown v. Board of Education (1954), the Supreme Court declared separate schools to be “inherently unequal” and outlawed segregation in schools. Desegregation efforts were slow, but succeeded in reducing the number of students in racially isolated schools. Despite problems—most prominently the phenomenon of within-school segregation, which led to minority students frequently being concentrated in the lower academic tracks—desegregation helped to narrow the achievement gap.

Since 1988, however, there has been a growing trend toward resegregation. The number of black students in the South attending predominantly white schools grew from 0.001 percent in 1954 to 43.5 percent in 1988, to again drop to 32.7 percent by 1998. Nationwide, the number of African American students attending schools with more than 90 percent African American students has grown from 62.9 percent in 1986 to 70.2 percent in 1998–1999. A new phenomenon is the increasing segregation of Latinos, who by 1998 experienced a higher degree of segregation than in 1968. This trend toward increasing segregation of Latinos and African Americans is concentrated in large cities, but also occurs in some smaller cities and in suburbs of large metropolitan areas.

Three reasons have been proposed to explain this trend. First, a growing Latino immigration, particularly in the West, has led to Latinos now making up the largest population in many major cities and older suburbs; second, residential segregation remains and thus contributes to the perpetuation of segregated schools. Residential segregation had become deeply entrenched in the first half of the twentieth century through public policy that disproportionately benefited whites and created predominantly white suburbs. Fair housing laws since the 1970s have had limited success in curbing ongoing discrimination in housing and mortgage markets.

“White flight,” or the tendency of whites to leave neighborhoods with growing numbers of black residents, has also been cited as a cause for a growing isolation of African Americans and Latinos in metropolitan centers. Charles T. Clotfelter’s study (2004) shows a trend toward integration in all areas of the United States, except in the Northeast. However, Clotfelter also identifies a series of “contrary forces” that have hampered or limited desegregation, several of which support the idea of a “white flight.” These include, first, whites avoiding mixed schools with high percentages of minority students; second, whites having options available to escape from desegregation (private schools, suburban schools, academic tracking, segregated school activities), while still appearing to support desegregation in principle; and third, white parents’ ability to exert pressure on track assignments, assuring their children attend predominantly white schools or classes.

One of the most far-reaching causes hindering further desegregation and preventing resegregation, however, is the alarming trend in Supreme Court decisions toward turning away from a commitment to integration. In Miliken v. Bradley (1974), the Supreme Court adopted a position of “suburban innocence.” Declaring that suburbs could not be held accountable for residential segregation, it decided against interdistrict busing, thus making it impossible to achieve integration in highly segregated school districts in Detroit. In Riddick v. School Board of the City of Norfolk (1986), the Supreme Court allowed districts to dismantle their desegregation efforts once they were integrated, or had achieved “unitary status,” even if such practices would lead to resegregation.

Two new large-scale and controversial educational reforms emerged in the 1990s: first, school vouchers, and later, the No Child Left Behind (NCLB) policy. Both moved the debate on school reform away from the goal of integration. The idea of school vouchers (1994) was to provide federal funding to parents who wanted to send their children to private schools, giving parents the right

to “choose,” irrespective of their financial status. Critics argued that only a fraction of students would have been able to be offered these funds, which typically would not cover the entire tuition. Poor students would likely be left behind in schools with declining student enrollment and public funds. While vouchers now only exist in a few metropolitan districts, the NCLB initiative became a nationally adopted reform in 2002, promising to overcome “the soft bigotry of low expectations” through rigorous high-stakes testing. Proponents argue that NCLB has increased achievement, but its critics counter that while it adds little to already well-achieving schools, it is damaging to the poorest ones with the most disadvantaged student populations. With NCLB forcing schools to produce significant and sustained improvement, but often without being granted adequate funding, many urban schools face the likelihood of failure or closure.

As of 2006, many Latino and African American students are attending schools with more than 90 percent Latino and black enrollment. While there is considerable debate about whether the resegregation of schools is due to public policy or to natural demographic changes across region and by race, few question that integrated schools, despite the problem of within-school segregation, tend to provide better conditions for students of color than segregated schools.

RESERVATIONS

SEE Affirmative Action.
monetary authority has to have sufficient holdings of foreign reserves to sell. For this reason, the central banks of many countries like to hold a substantial amount of foreign reserves to protect themselves from external shocks that could cause sharp depreciation of their currency, such as a sudden outflow of foreign investment from the country or a sudden drop in export revenues.

The amount of foreign reserves is particularly important for countries that follow a fixed exchange rate regime—that is, they commit to maintaining the value of their currency at a preannounced level. In many cases, such policies were adopted in order to anchor inflationary expectations and lower the level of inflation. In these cases, inflationary pressure in a flexible exchange rate regime would lead to currency depreciation. When the exchange rate is fixed, the monetary authority has to keep spending its foreign reserves to maintain the promised level of the exchange rate. Most of such fixed exchange rate regimes ended in currency crises, also known as balance-of-payments crises, because monetary authorities ran out of foreign reserves. Sometimes the currency crisis in such a situation can be delayed through currency devaluation, when the fixed exchange rate is reset to a new level. The most commonly used model that links foreign reserves to currency crises was developed in Paul Krugman’s 1979 article “A Model of Balance-of-Payments Crises,” modified later by Robert Flood and Peter Garber in their 1984 article “Collapsing Exchange Rate Regimes: Some Linear Examples.”

CURRENCIES USED FOR FOREIGN RESERVES

Historically, the currencies used for foreign reserves were largely dictated by the exchange rate policies in the economies that used paper money. Initially, when paper money was introduced, in order to make people believe in its value, many countries tied the value of the paper money to gold or silver—each banknote could be redeemed at the central bank in exchange for the amount of gold or silver indicated on that banknote. Such an arrangement required the central bank to hold sufficient reserves of gold or silver to exchange all of the banknotes it printed for precious metal. If the central bank did not have sufficient reserves, it would devalue the paper currency by lowering the amount of precious metal the holder of the banknote could obtain.

Under the Bretton Woods arrangement (1944–1971), participating countries’ currency values were tied to the U.S. dollar, while the value of the U.S. dollar was tied to gold. Thus, the Federal Reserve System, the central bank of the United States, would hold foreign reserves primarily in gold while other countries held their foreign reserves primarily in U.S. dollars. As a rule, countries that adopt fixed exchange rates tend to hold their foreign reserves in the foreign currency to which they tie the value of their national currency.

Most countries, regardless of their exchange rate regime, hold their foreign reserves in hard currencies, currencies that are known to have low inflation: the U.S. dollar, the euro (before the existence of the euro, the German mark), or the Japanese yen. As of 2004, as much as 75 percent of total world foreign reserves were held in U.S. dollars. This U.S. dollar dominance is due mainly to the fact that many countries held the U.S. dollar as their foreign reserves during the Bretton Woods period. In addition, as Cedric Tille and Linda Goldberg argue in “Vehicle Currency Use in International Trade” (2005), much of this dollar dominance today is due to the fact that most international trade is invoiced in U.S. dollars. Nevertheless, this need not be the case in the future—as Menzie Chinn and Jeffrey Frankel show in “Will the Euro Eventually Surpass the Dollar as Leading International Reserve Currency?” (2005), the euro may surpass the U.S. dollar in the role of major currency as early as 2020, mostly due to a substantial depreciation of the U.S. dollar from 2001 to 2005.

RESIDUALS

To define the notion of residuals, let us introduce a linear model describing the relationship between $K + 1$ inde-
pendent variables $x_j$ with $j = 0, 1, 2, \ldots, K$ and a dependent variable $y$:

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_K x_K + u$$

with $u$ being the stochastic error representing all factors affecting $y$ not included in the $x_j$’s.

Assuming $E(u|x) = E(u) = 0$, the population regression function is:

$$E(y|x) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_K x_K$$

This is estimated by the sample regression function:

$$\hat{y} = \beta_0 + \hat{\beta}_1 x_1 + \hat{\beta}_2 x_2 + \ldots + \hat{\beta}_K x_K$$

where $\beta_0, \beta_1, \ldots, \beta_K$ identify a set of estimated parameters calculated using the estimation rule $\hat{\beta}$.

Assuming a sample of $N$ observations, the residual for observation $i$, with $i = 0, 1, 2, \ldots, N$, is the difference between the actual value of $y_i$ and the fitted value of the estimated regression, that is:

$$\hat{u}_i = y_i - \hat{y}_i = y_i - \beta_0 - \beta_1 x_{i1} - \beta_2 x_{i2} - \ldots - \beta_K x_{iK}$$

If the residual is positive, the estimated regression underpredicts $y_i$ and vice versa if the residual is negative. Each residual $\hat{u}_i$ can be interpreted as an estimate of the unobservable error $u_i$, and as such can be employed in constructing a number of statistical tests assessing the properties of the estimated model and a set of indicators determining the goodness of fit.

Ideally, a good model is characterized by small residuals, that is, by fitted values $\hat{y}_i$ that are close to the actual values $y_i$. The ordinary least squares (OLS) estimator of the parameters $\beta$ is calculated by fitting the regression line that best approximates the data through the minimization of the sum of squared residuals. The resulting first-order conditions for the OLS estimator are $\sum_{i=1}^N \hat{u}_i = 0$ and $\sum_{i=1}^N x_{ij} \hat{u}_i = 0$, with $j = 1, 2, \ldots, K$.

As regards the goodness of fit, defining the total sum of squares $SST = \sum_{i=1}^N (y_i - \bar{y})^2$, the explained sum of squares $SSE = \sum_{i=1}^N (\hat{y}_i - \bar{y})^2$, and the residual sum of squares $SSR = \sum_{i=1}^N \hat{u}_i^2$, the part of variation in $y$ that is explained by the regressors, is given by the coefficient $R^2 = 1 - SSR/SST$. $R^2$ is between 0 and 1, with the fit of the regression improving as $R^2$ approaches 1. A consistent estimator of the variance of the stochastic error is given by $\hat{\sigma}^2 = (N - K - 1)^{-1} \sum_{j=1}^N \hat{u}_j^2$. Its square root $\hat{\sigma}$ is then an estimator of the standard deviation of the unobservable factors affecting the dependent variable $y$. It indicates how well the model predicts $y$ given the information set represented by the observables $x_i$’s. The estimate $\hat{\sigma}$ is used to construct the standard error of the OLS estimator, equal to $se(\hat{\beta}_j) = \hat{\sigma} / \sqrt{SST(1 - R_j^2)}$ where $SST_j$ is the total sum of squares of $x_j$ and $R_j^2$ is the $R^2$ of the regression of $x_j$ on all other regressors. The standard error $se(\hat{\beta}_j)$ is then employed to test for statistical significance of each estimated parameter through the $t$-statistic.

If the errors were homoskedastic, we would have that $Var(u|x_1, x_2, \ldots, x_k) = E(u^2|x_1, x_2, \ldots, x_k) = E(u^2) = \sigma^2$. On the contrary, in the presence of heteroskedasticity the expected value of $u^2$ can be assumed to depend on some function of the explanatory variables. Following this logic, Breusch and Pagan suggest a test for heteroskedasticity that consists of an $F$-test on the regression of the squared residuals on the explanatory variables. The White test for heteroskedasticity simply consists of a similar regression including nonlinearities, that is, the squares and cross-products of the explanatory variables.

White suggests using the residuals $\hat{u}_i$ to calculate a heteroskedasticity-robust standard error for $\hat{\beta}_j$. This is given by $se_{robust}(\hat{\beta}_j) = \sum_{i=1}^N \hat{u}_i^2 / SSR_j^2$, where $\hat{u}_i$ is the $i$-th residual of the regression of $x_j$ on all other regressors and $SSR_j$ is the residual sum of squares of this regression.

**RESILIENCY**

**Resilience** is an increasingly common term used in concept in various branches of psychology, in particular developmental psychology, severe mental illness (SMI), trauma studies, disaster response, social psychology, and “positive” psychology. Across all of these areas of psychological investigation, resilience refers to the human ability to have withstood, or to be able to withstand, challenge, crisis, stress, or trauma of differing types.

In their 1998 work, researchers Ann Masten and J. Douglas Coatsworth conceptualize resilience as “manifested competence in the context of significant challenges
to adaptation or development” (p. 206). Thus they believe, as Nancy Davis noted in 1999, that there needs to have been a considerable menace to a person or an actual traumatic experience and, in spite of this, the individual’s quality of adjustment or development is nevertheless good.

According to Masten and Coatsworth in 1998, in the area of clinical psychology and psychopathology, Norman Garmezy is considered to be a “peerless pioneer in the study of competence and resilience.” This accolade is the result of his groundbreaking work examining adults with schizophrenia and their functioning that is adaptive as well as dysfunctional and the children of parents with schizophrenia. In investigating the risk factors for these children, vis-à-vis their developing schizophrenia, Garmezy and his colleagues found that while having a parent with schizophrenia does indeed increase an offspring’s likelihood for subsequently developing schizophrenia, they were amazed that their investigation indicated that ninety percent of those they surveyed did not develop the illness. He noted that their subjects upset predictions and, in fact, displayed many qualities that arise from good peer relations, including academic achievement and purposeful goals. Garmezy stated in 1971, “Were we to study the forces that move such children to survival and to adaptation, the long range benefits to our society might be far more significant than our many efforts to construct models of primary prevention designed to curtail the incidence of vulnerability” (p.114). He went on to explore what it was that seemed to protect these offspring and, as a parallel result, the scientific investigation of resilience began.

Subsequently, developmental researchers have conducted studies that are not just within psychopathological areas, but other stressful environments such as neglectful or abusive parents, war zones and environments of high poverty, or children who have physical illness. One of the leading authorities in the field, Michael Rutter, noted concerns with early conceptualizations of resilience, with individuals being referred to as “invulnerable” or “invincible.” Davis reports in 1999 that Rutter’s point is that vulnerability to stress is a continuum, not all-or-none, and some people may display better resilience in response to some stressors, but this may not be uniform across all stressful situations or at all times. Thus, someone is not very likely to be invincible in the face of all adversities. Rutter notes in 1991 that the features that contribute to resiliency will vary in response to risk mechanisms and that resiliency may be contingent as much on social context as on the individual. As a result, rather than being a static characteristic, resiliency is affected by developmental changes (pp. 1–2).

What may seem a rather straightforward concept or construct may indeed not be. In fact, Suniya Luthar notes in 1993 that “overt social competence among high risk individuals is not necessarily paralleled by superior adjustment on covert mental health indices” (p. 441). This may seem surprising or even counter-intuitive. For example, in her study of adolescents who appeared socially competent and who were in stressful situations, Luthar found that they actually self-reported experiencing high levels of mood problems such as anxiety and depression.

Marian Radke-Yarrow and Elisa Brown conducted a 10-year longitudinal study of children with parents who were diagnosed with mood disorders, which they reported in 1993. When they compared resilient offspring to control offspring, they discovered that 56 percent suffered from somatic complaints, versus only 21 percent of the cohorts. This raises the question asked by George Vaillant: “Does resilience merely mean survival in the face of vulnerability and multiple risk factors, or should we think of resilience only when it also permits happiness? Is it enough that the vulnerable patient survives the operation and that the orphan survives the concentration camp, or, in addition, should they be able to run and laugh and feel joy as well?” (1993, p. 285).

Resiliency is much less focused on an individual’s deficits or psychopathology in the face of trauma or adverse conditions. For example, Emmy Werner and Ruth Smith consider resiliency to be a “self-righting capacity” involving not only the individual but including the support that comes from loved ones, schools, or even communities that all conspire to aid in one’s healthy responses or healing. Thus, when adversity strikes, the individual is able to compensate or “self-right.” They believe that all people have some innate self-righting capacity (Werner and Smith 1992, p. 202).

**CHARACTERISTICS OF RESILIENT INDIVIDUALS**

The Ego-Resiliency (ER) construct views individuals as being able to demonstrate “resourceful adaptation to changing circumstances and environmental contingencies, (ability to) analy(z)e the ‘goodness of fit’ between situational demands and behavioral possibility, and (have an) ... available repertoire of problem-solving strategies,” as reported by Jeanne H. Block and Jack Block in 1980 (p. 48). In 1996 Eva Klohnen summarized characteristics of resilient individuals as including the ability to be happy and contented, with a sense of direction and purpose; the capacity for productive work and a sense of competence and environmental mastery; emotional security; self-acceptance; self-knowledge; a realistic and undistorted perception of oneself, others, and one’s surroundings; interpersonal adequacy and the capacity for warm and
Resiliency

caring relating to others and for intimacy and respect; confident optimism; autonomous and productive activity; interpersonal insight and warmth; and skilled expressiveness.

Resiliency, as conceptualized as Ego-Resiliency, has been measured using the California Adult Q-Set (CAQ), as Jack Block noted in 1978. The Q-set is a number of atheoretical, descriptive personality items used in the CAQ. This instrument used a Q-sort methodology and is thus fairly time consuming. A Q-sort is a sorting task made up of descriptive personality characteristics on cards that require a subject to sort or rank order the cards from high to low relevance to the subject's self-perceived personality characteristics (Stephenson, 1936). In 1996 Klohnen developed an empirically derived, 29-item self-report scale that has good internal consistency, good reliability, substantial convergent validity with the CAQ-based observer measure, and solid external criterion validity with another index of psychological adjustment.

RISK FACTORS
Risk factors in resilience research are defined by Jon Rolf and Jeannette Johnson in 1990 as "those variables that have proven or presumed effects that can directly increase the likelihood of a maladaptive outcome" (p. 387). Various studies issued by Peter Fonagy, Miriam Steele, Howard Steele, Anna Higgitt, and Mary Target in 1994, by Masten and Coatsworth in 1998, Lois Barclay Murphy and Alice Moriarty in 1976, and Werner in 1996 have discovered an almost limitless number of risk and stress factors. These factors include but are not limited to genetic abnormalities, developmental delays or irregularities, lack of education, poverty, parents with chronic or mental illness, death of a close family member, familial violence, and war, as well as constitutional vulnerabilities such as sensory-motor deficits and insufficient impulse control.

PROTECTIVE OR PROMOTIONAL FACTORS
Masten and Coatsworth noted in 1998 that resilience studies are "remarkably consistent in pointing to qualities of child and environment that are associated with competence or better psychosocial functioning during or following adverse experiences" (p. 212). For the individual these include good intellectual functioning; an easygoing disposition; self-efficacy; self-confidence; high self-esteem; talents; and faith. Familial qualities include a child having a close relationship with a caring parent figure; authoritative parenting that provides warmth, structure, and high expectations; socioeconomic advantages; and connections to extended supportive family networks. Outside the family, bonds to pro-social adults, connections to social organizations, and attendance at effective schools also contribute to an individual's resiliency.

Naimah Weinberg, Elizabeth Rahdert, James Collliver, and Meyer Glantz's 1998 meta-analysis suggests that "while there is no single 'resilience' trait," such qualities as those noted above seem to hold some protective ability. Edith Grotheberg, through her works in 1995 and 1998, offers a different conceptualization from her international work, suggesting that to overcome adversities, people draw upon as many as fifteen sources of resilience. They include such factors as having people around that are trusted and loving, being a person that people like and love, and being able to find someone to help when needed, for example.

PREDICTORS OF RESILIENCY
A review of the literature compiled by Davis in 1999 resulted in a list of predictors structured within areas of competency. These issues should be interpreted with the caveat that "all of these characteristics are only known to correlate with resilience; they are not necessarily causes. In fact, Davis says they could just as well be consequences of success rather than causes of it" (1999). Having more is better, but absence is not catastrophic.

- Physical Competence: Good health, easy temperament, and good prenatal care.
- Social and Relational Competence: Secure parental attachment and basic trust, ability to reflect upon the mental states of oneself and others, ability and opportunity to recruit actively people who can help, strong ability to make and keep a few good friends, positive peer relationships, interpersonal awareness or role-taking abilities, and empathy.
- Cognitive Competence: Average to above average intelligence quotient and emotional (intelligence) quotient, good language acquisition and reading ability, capacity to plan/have foresight, good problem-solving abilities, positive future expectations, internal locus of control, assertiveness, and optimism.
- Emotional Competence: Emotional regulation, ability to delay gratification, realistically high self-esteem, sense of autonomy, ability to think and work creativity, and a sense of humor.
- Moral Competence: The ability and opportunity to contribute.
- Spiritual Competence: Having faith that one's own life matters, and conviction that there is a meaning to what one does.
RESILIENCY TRAINING

A number of social support and stress inoculation programs were developed in the 1990s. These programs used methods of outdoor education, classroom simulations, and other methods in community intervention efforts. Davis noted in 1999 that these programs include family skills training, strengthening families program, Focus On Families, Families and Schools Together, Family Effectiveness Training, behavioral family therapy, structural family therapy, functional family therapy, Parenting Adolescents Wisely, Kempe Prevention Research Center for Family and Child Health, Dare to Be You, Be A Star, Learn and Service America, Say It Straight, Big Brothers/Big Sisters of America, Adventure Education, and Outward Bound.

In 2002 the American Psychological Association developed a program that is publicly available titled *The Road to Resilience*. It involves a combination of media (television such as the Discovery Health Channel, Web sites, printed materials) through which psychologists could gain training and provide lectures in communities.

RESISTANCE

The concept of *resistance*, meaning literally to stand against, entered the social sciences primarily from politics and culture. While there is a clinical psychoanalytic definition of the term, and a technical one used by the physical sciences, it is really resistance in a critical politico-cultural sense that has had the greatest impact in the field.

Resistance in a political context is often thought of as the property of the left. The famed French (and often communist-led) *Résistance* against the Nazi occupation
immediately comes to mind. But the concept was first introduced into the modern political lexicon from the right, by Edmund Burke, who argued for the necessity of resisting revolutionary “progress” in his *Reflections on the Revolution in France* (1790). Burke was incensed at the French overthrow of birthright authority and the leveling of classes (he was particularly horrified by the thought of the hairdresser who thinks himself the equal of his betters). These, and other such revolutionary abuses, fly in the face of time-tested tradition and threaten to upset the natural order of things. As such, it is the “best wisdom and the first duty” of every Englishman to stand against such radical change, with “jealous, ever-waking vigilance” (p. 54).

The conservative call for a resistance against change was taken up by Burke’s countryman Matthew Arnold. By the mid-nineteenth century the republican ideals of the French revolution had the lead over Burke’s beloved tradition, and nature, after Darwin, was harnessed to progress. A new principle of resistance was needed—and for Arnold, it was culture. As “the best that has ever been thought and said” (as he defines it in *Culture and Anarchy*, 1869), culture offered a means with which to rise above the politics, commerce, and industry of the day and supply a universal standard upon which to base authority and order.

Karl Marx, exiled in England when Arnold was writing, also thought resistance a conservative ideal. In their 1848 *Communist Manifesto* Marx and Engels paint a heady portrait of dynamic change: traditions overthrown, nature transformed, nations dissolved, people uprooted; a world where “all that is solid melts into air” (p. 38). For Marx, resistance is *not* the answer—it’s the problem. It is capitalism’s bourgeois caretakers who are resisting the system’s own logic. Capitalism has socialized the means of production, yet ownership is kept in the hands of the few. The revolutionary solution is to tear asunder this final resistance and herald in the new world.

*Resistance* moved leftward with the anticolonial struggles of the twentieth century. Mohandas K. Gandhi, waging a battle against British rule in India, advocated a political philosophy of *satyagraha*. In Sanskrit this word means “insistence on the truth,” but Gandhi also used it to denote “civil resistance.” This conflation of meanings makes a certain sense, as for Gandhi it was the untruths of colonial rule—that power must rest upon violence, that English culture comprised the “best that has ever been thought and said”—that needed to be resisted more fiercely than even the British themselves. To be free of European bodies on Indian soil was one thing; to be free of their ideas, their prejudices, and their technology was another. Drawing upon both Burke and Arnold, but turning these ideas on their head, Gandhi advised the practice of civil disobedience, not merely in the streets, but through a political and spiritual return to traditional Indian culture and practices like *khaddar*, the hand-looming of cloth.

Radical resistance, defined in part as the rejection of foreign cultures and the celebration of indigenous traditions, spread across the globe as European colonies in Africa and Asia were overturned by struggles of national liberation. Gandhi’s strategy of nonviolent civil disobedience was not adopted by all. The Caribbean psychiatrist-cum-rebel Frantz Fanon made the case for bloody resistance in his influential *The Wretched of the Earth* (1963). Indeed, for Fanon it is the very violence of the resistance that will clear the way to a new society. But for all their differences, Gandhi and Fanon agreed on one thing: that the enemy that one had to resist the most virulently was the enemy one had internalized—what the Tunisian writer and activist Albert Memmi referred to in his 1957 book *The Colonizer and the Colonized* as “the colonizer within.”

The concept of resistance returned to the West via concerns with identity and identity-construction. In the early 1960s the American sociologist Erving Goffman argued that the job of total institutions like prisons, hospitals, and armies is to create—or recreate—their charge’s identity in order to integrate them into the system. However, Goffman observes, the patients in the mental institution he studied actually formed their identities by eliding institutional demands and creating “underlives” within the institution. In brief, it is in resisting the definitions pressed upon them that inmates develop their own sense of identity: “It is against something that the self can emerge” (p. 320). Goffman’s book, *Asylums* (1961), was not merely a critique of total institutions, but a critical assessment of the postwar “Free World” of big business and the welfare state, mass media, and compulsory education—a mostly benign, but nonetheless totalizing system.

It was in resistance to this benign totality—the ticky-tacky little boxes where everyone comes out all the same, as Pete Seeger sang in 1962—that a youth counterculture emerged in the 1960s, as young people created “underlives” by defining themselves against The System. Some of this resistance was political—opposition to the American war in Vietnam, for instance—but it was also a stylistic confrontation: new styles of clothes, forms of music, and types of intoxicants. In other words, it was *cultural resistance*.

The idea, and ideal, of cultural resistance, while first championed by Matthew Arnold, takes its radical articulation from the Italian Marxist Antonio Gramsci. Gramsci held that hegemony is both a political and cultural process and thus part of the revolutionary project is to create a counterhegemonic culture. But if this culture is to have
real power, and radical integrity, it cannot—contra Arnold—be imposed from above; it must come out of the experiences and consciousness of “the people.” Thus, the job of the revolutionary is to discover the progressive potentialities that reside within popular consciousness and from this material fashion a culture of resistance.

It was this implicit politico-cultural mission that guided the Centre for Contemporary Cultural Studies (CCCS) at the University of Birmingham in the 1970s. The CCCS is best known for its study of subcultures, and it was within mainly working class subcultures— punks, mods, skinheads, and Rastafarians—that researchers found an inchoate culture of resistance. For Stuart Hall and his CCCS colleagues, however, cultural resistance was politically ambiguous. Subcultures opened up spaces where dominant ideology was contested and counter-hegemonic culture was created; at the same time, these contestations and symbolic victories often remained purely cultural, leaving the political and economic systems untouched. Cultural resistance, unless translated into political action, becomes what Hall and others referred to as “imaginary” solutions to real-world problems (Hall 1976).

This raises a nagging question that dogs the whole project of politico-cultural resistance. Is this resistance really resistance at all? The efficacy of cultural resistance has been questioned since at least 1934, when Malcolm Cowley, reminiscing about his Greenwich Village life in Exile’s Return, pointed out that while bohemians may have flouted Victorian values of thrift and savings, their libertinism and emphasis on style and innovation mesh quite nicely with the needs of consumer capitalism. As the Frankfurt School theorist Theodor Adorno snidely remarked about the jazz fan of the era, “he pictures himself as the individualist who whistles at the world. But what he whistles is its melody” (Adorno 1938, p. 298). Resistance as a political strategy also has its critics. Resistance only exists in relation to the dominant power—“bonds of rejection” is what Richard Sennett calls this relationship in his discussion of Authority (1985)—and without that dominant power, resistance has no coherence or purpose. What, then, is the point of resistance if it rests on the maintenance of the very thing being resisted?

Michel Foucault, like his contemporary Erving Goffman, studied total institutions—prisons, asylums, and schools—but the French intellectual was interested in institutions of the mind as well: disciplinary boundaries and classification systems. The failures of radical political resistance in 1968 confirmed what Foucault had already known: that power was not something “out there”—easy to identify and overthrow. Instead, it was everywhere, continuous, anonymous, intimate, and even pleasurable: “the disciplinary grid of society” (p. 111), as he names it in Power/Knowledge (1980). For most critics, the individual subject/self is the hero of resistance against totalizing control; Foucault countered that the subject itself was problematic. The Enlightenment’s focus on the subject allowed for new ideals of personal freedom, but it also opened up new sites of oppression: the individual’s mind, body, and spirit. Because power is impressed upon and internalized in the subject, it raises a vexing problem: Who is it that resists and what exactly are they resisting? Can one resist the very subject doing the resisting? Resistance remains a stated goal for Foucault, but one that must be reconceptualized. The ideal of developing the pure subject in opposition to the corrupting object of society must be rejected. “Maybe the target nowadays,” he suggests in “The Subject and Power” (1984), “is not to discover what we are, but to refuse what we are” (p. 208).

This idea of resistance is played out to its—perhaps illogical—conclusion by the playful postmodernist Jean Baudrillard. In his 1985 essay “The Masses: The Implosion of the Social in the Media,” Baudrillard argues that strategies of resistance always change to reflect strategies of control. Against a system that excludes or represses the individual, the natural demand is one of inclusion: to become a subject. Today, however, people are bombarded with appeals for their participation—and yet they still feel that their choice or vote matters little. Against a system that justifies and sustains its existence by the political consent (or consumer purchases) of those it governs, the masses have devised a new strategy of resistance: apathy, “a massive desisting from will” (p. 109). A resistance to resistance.

Another path taken has been to move beyond resistance—to reimagine identities and politics not tied to the negation of the other. Michael Hardt and Antonio Negri sketch a bleak portrait of an all-pervasive, omnipotent system of control: Empire (2000). They acknowledge that within such a system, political and cultural resistance is usually expressed in a generalized “being-against”—a negative resistance. Yet they also see the chance for something different. They argue, like Marxists before them, that the system itself is generating the very tools and social conditions that make transcendence possible. The system of Empire relies upon new communication flows, new forms of organization, and new subjectivities—all of which might give rise to radical identities, ideals, and collective actions not mired in the negation of being-against, thereby offering the subjectivity necessary for proactive social change, that is: a “being-for.” The boldest, and perhaps most outrageous, proposal to move beyond resistance comes from the Slovenian philosopher Slavoj Žižek who, drawing upon ideas of Jacques Lacan in The Ticklish Subject (1999), proposes something he calls “the Act”—a radical act that jumps outside the coordinates of the dominant system, including any opposition tied to these coor-

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION 209
dinates. This act transcends resistance and its attendant disobedient obedience—but one might also legitimately ask: Where does an act like this lead?

RESOURCE ECONOMICS

As a subfield of economics, resource economics examines the allocation of natural resources between uses and over time. Natural resources have enjoyed a prominent role in the history of economic thought. French physiocrats François Quesnay (1694–1774) and Anne Robert Jacques Turgot (1721–1781) considered in the mid-eighteenth century that agriculture (land) creates all value and supports manufacturing and service sectors in the economy. Land had a central role also in classical political economy, particularly in the works of English political economists Thomas Malthus and David Ricardo. Later in the late-nineteenth century, English economist Stanley Jevons (1835–1882) devoted attention to coal as the crucial natural resource for industrialization and growth in Great Britain.

Land economics emerged in the United States in the early decades of the twentieth century as the immediate predecessor of natural resource economics; this body of theory addressed economic issues related to agriculture and agricultural land in particular. Economists have developed major theories in resource economics since the 1930s. Harold Hotelling (1895–1973) suggested that reserves of nonrenewable resources such as ores, coal, and oil could be considered capital assets. They can either be extracted now or left for the future to appreciate in value. The decision to extract the reserve depends on the relative returns of the two alternatives. Hotelling argued that the optimal extraction rate of a resource equates the change in its net price (price net of extraction costs) with the interest rate or the rate of return from other capital assets. This is known as the Hotelling Rule. Its significance lies in underlining the role of interest rate in extraction decisions.

Economist H. Scott Gordon (b. 1924) and fisheries scientist Milner B. Schaefer (1912–1970) produced the key insights into renewable natural resources when they combined biological and economic models of fisheries. The biological model postulates a bell-shaped relationship between a fish population (stock) and its growth. Key aspects of the model also include a minimum viable stock level and the natural equilibrium (or natural maximum stock level), and the maximum sustainable yield at some intermediary level of stock. This biological model can be transformed into an economic one by assuming constant prices for the fish and a direct relationship between the fishing effort and the size of stock, and by recognizing that harvesting involves cost. The bell-shaped relationship now depicts the revenue from fishing, while total costs of harvesting increase monotonously with fishing effort. The efficient level of catch is achieved at a level of harvesting below maximum sustainable yield when the net benefits as the difference between revenue and cost are maximized. However, in the case of open access fisheries, it is prof-
itable for fishermen to increase their catch until their marginal revenue equals their marginal costs. While individually rational, this results in excessive and economically inefficient harvesting, and suggests controlling of harvesting levels by regulating gear or imposing catch quotas. More recent work in resource economics, such as that of economist V. Kerry Smith, frequently focuses on the monetary valuation of non-market environmental harms, risks, and benefits.

Other contributions to understanding natural resource use and problems associated with it have come, for example, from environmentalist Garrett Hardin (1915–2003). His application of game-theoretic ideas to the use of pastures and other natural resources, in 1968, popularized the notion of the Tragedy of the Commons as an explanation for the degradation and depletion of renewable natural resources. While Hardin erred in attributing the destructive competition for resources to the commons (instead of open access to a resource), his game theoretic analysis of natural resource use problems shifted attention away from the conditions of optimal inter-temporal allocation to factors which engender nonoptimal outcomes and institutional arrangements that can assist in avoiding them. New institutional scholars such as Elinor Ostrom have popularized this approach in research on the use and management of renewable natural resources since the early 1990s.

**RESOURCES**

A resource is anything of value as an input in production. Classical political economy identified land, labor, and capital as the three factors of production, and in this way it distinguished between natural resources, human resources, and financial resources. Capital could be understood merely as physical instruments of production, but, for example, William Stanley Jevons (1871) considered a sum of money or financial resources a transitory form or capital that could be transformed into physical instruments of production. Whereas human resources and financial resources are terms that are still in common usage, the term resources can also be used more narrowly to refer to natural resources only. This is the sense in which resources are discussed in this article.

Natural resources are conventionally divided into three categories: indestructible or nondepletable, renewable or depletable, and exhaustible or nonrenewable resources. Examples of nondepletable resources include wind and solar energy, whereas fisheries, pastures, forest resources, and soils are examples of renewable resources. Minerals, ores, coal, and oil are exhaustible resources. Sometimes the term exhaustible resources is also used to refer to both renewable and nonrenewable resources. A broader definition of environmental resources would include newly discovered or defined resources such as biodiversity, the ozone layer, and atmospheric and other sinks, in addition to conventional natural resources. Most of these resources are best understood as renewable or depletable resources.

Exhaustible resources are categorized further by the U.S. Bureau of Mines and the U.S. Geological Survey (1976) on the basis of the economic feasibility of their extraction and the state of knowledge on their quantity and quality: Resources are identified or undiscovered, and economic or subeconomic. Identified and economic resources constitute reserves. Reserves, such as those of oil, increase when technology changes and reduces extraction costs, making it economically feasible to extract previously identified but subeconomic resources. New discoveries can also increase reserves if it is economically feasible to extract them.

The 1972 book *The Limits to Growth: A Report for the Club of Rome's Project on the Predicament of Mankind* (Meadows, Meadows, Randers, and Behrens 1972) raised concerns upon its publication regarding the future availability of key resources. Its computer simulations, which were based on the postwar experiences of high population and economic growth and the prevailing technological performance of the time, suggested that a continuation of resource use as it was happening would result in the exhaustion of many important resources such as oil, coal, and metals in a few decades. However, the standard eco-
nomic argument is that when resources become scarcer, new stocks are called into reserves by increasing prices. Price increases also give incentives for technological development and new discoveries that harness new resources to replace the ones that are exhausted. The exhaustion of resources is not a problem from an economic point of view if the proceeds from resource use can be invested in a way that compensates for the loss of economic returns from the resource use.

While the predictions of the report have not become literally true, some general trends have played out: Population growth, increasing income levels, and globalization have put pressure on renewable resources, in particular, to such an extent that physical scarcity and absolute limits have to be taken seriously. In their article “Human Appropriation of the Products of Photosynthesis” (1986), Peter M. Vitousek and his coauthors estimate that humans consume 40 percent of total terrestrial net primary production. Boris Worm and his coauthors in “Impacts of Biodiversity Loss on Ocean Ecosystem Services” (2006) find that global fish landings have diminished since 1994 despite significantly increased fishing efforts, and that the main commercial fisheries are likely to collapse in the coming decades if marine biodiversity is not protected effectively. In their article “Tracking the Ecological Overshoot of the Human Economy” (2002), Mathis Wackernagel and his coauthors estimate that the global mean ecological footprint is 2.3 hectares per person, but it is twice that figure in Europe and four times higher in the United States. This means that many developed countries have to import carrying capacity, often from the developing world, as described by Marc L. Imhoff and his coauthors in “Global Patterns in Human Consumption of Net Primary Production” (2004). The global ecological footprint, the area needed to produce the goods and resources that humanity uses, currently amounts to 1.3 Earths. According to the authors, we currently overshoot the carrying capacity of the earth by a large margin.

RESTITUTION PRINCIPLE
The theory of restitution is a neglected aspect of international and national income accounting. The concept addresses the problem of how to measure, and account
for, the costs and benefits of systemic economic injustice. What are the economic consequences of longstanding, historically grounded, systemic exploitation, wrongful taking, unjust enrichment, unequal exchange, immoral accumulation, and excessive profiteering based on racial, ethnic, religious, or language-cultural domination and control? Restitution theory provides a basis for understanding and analyzing problems of chronic poverty and inequality, and developing rational public policy remedies.

A related concept is the restitution principle. It is a moral concept that says that if a society democratically decides that certain practices, such as slavery, segregation, and discrimination, are wrong and makes them illegal, then it is not morally acceptable to retain class pecuniary benefits that were produced by those past practices. These benefits must be returned to the class from which they were taken. Whenever there are chronic grievances—between nations, races, or other large social groups—a fundamental issue is invariably the sense that one party has systematically perpetrated unremedied economic injustices.

The theory of restitution is based on the intuition that it is possible to:

- Reconstruct historic economic relations.
- Specify “fair” standards for prices, wages, terms of trade, and interest rates.
- Specify fair rates of return on investments that were violated, usually by force.
- Audit the historic pattern of transactions between the groups in question.
- Compare the actual with the “fair” standard, then estimate the deviation from “fairness.”
- Designate that result as unjust enrichment, and estimate its present value and distribution.
- Draw policy implications that will usually lead to remedies in the form of lump sum or other redistributive income and wealth transfers, in-kind subsidies, or investments in real and human capital.

In the case of African Americans, for example, for four hundred years, income and wealth have been coercively diverted from Africans and African Americans to the benefit of Europeans and European Americans. This was primarily done through slavery, then Jim Crow segregation, and then discrimination in education, housing, and labor and capital markets. It is possible now to reconstruct that history in detail, develop national income accounting tools to regularly measure the magnitude of income and wealth transfers, then estimate their present value and distribution.

These unjust enrichments were not dissipated. They were transferred intergenerationally and are currently held by whites in the top 30 percent of the income and wealth distribution. The processes that produced the benefits are now widely regarded as wrong, illegal, and illegitimate. They violate current standards of fairness; therefore, the benefits these processes produced are unjust, and should be returned to those who were harmed or to their descendants collectively.

This becomes a matter of restitution. And the restitution owed—by some estimates, $5 to 10 trillion—can be paid through adjustments in tax and budget policies over approximately forty years. The restitution could also be paid primarily through investments in human capital, housing, and business formation.

U.S. national income accounts do not help much in managing social dysfunction. They overlook unjust enrichment. Similarly, U.S. international income accounts overlook systemic unequal exchange—overcharges and underpayments between trade and investment partners who have asymmetric power and bargaining strength. Without proper accounting, policymakers produce weak concepts and weak policies and programs that fail to remedy problems of poverty and underdevelopment. Scholars and policymakers do recognize disparities and inequalities, and the basic reasons for continuing chronic economic distress, among many African Americans, have been thoroughly documented. But the descriptions and analyses do not produce policies sufficient to manage or solve the phenomenon of gross disparities in income and wealth by race. Economists and other social scientists and policy analysts have focused on the costs of racial exclusion and discrimination. But that is an incomplete approach, and one reason that relatively little progress has been made against intransigent, chronic economic underperformance and persistent poverty.

The concept of restitution is based on the understanding that justice and morality are fundamental to sound public policy. And retaining unjust enrichment is inconsistent and incompatible with holding in perpetuity benefits derived from past immoral and wrongful systemic transactions and processes. Americans, for example, can acknowledge that much wealth has been built in the past by methods that cannot stand scrutiny by today’s standards, even though such methods may have been acceptable at the time. But morality according to the restitution principle makes it impossible to accept the fruits of wrongful actions that were committed on one’s behalf—as posterity—by one’s collective if not direct biological ancestors.

Boris Bittker’s *The Case for Black Reparations* (1973) examined these questions thoroughly and successfully. He dealt with all the common objections—that raising these issues now, so late in the game, is ex post facto, and that justice is not meted out that way under the American sys-
Restitution Principle

In response, Bittker argued that there is ample precedent for finding retroactive responsibility and culpability, and correcting it, if practicable. As part of national and international accounting, government and nongovernmental agencies can perform the statistical and analytical work in the process of managing national economic life.

In the U.S. case, slavery, primarily agricultural slavery, produced benefits for over two hundred years. But many Americans only think of slavery in terms of agricultural commodity production. In fact, slavery generated great benefits in other ways as well. Slaves were used in manufacturing, services, and activities that today would be called municipal or state government, running transportation, utility, and emergency services. Enslaved people also cleared land and built infrastructure—roads, dams, levees, canals, railroads, and bridges. Without this labor, it can be argued, the United States would not have expanded west as it did. Indeed, it is possible, and perhaps probable, that the United States would never have become a continental nation. It likely would not have been able to complete the Louisiana Purchase, nor gain the territories that became the Southwest and West Coast states, so vital to twentieth-century growth. Without the labor of enslaved people, the United States could well have ended, territorially, at about the Mississippi River, and never emerged as a world power. The point is not to speculate on counterfactual history, but the crucial role of slave labor in creating the basis for expansion and total continental development is worth underlining.

Slave-produced goods and services benefited most white Americans indirectly and passively through the process of human capital formation. Slaves made it possible for many whites to go into more rewarding occupations, gain increased skills, and generate greater lifetime earnings for themselves and their descendants. In these indirect and passive ways, slavery produced enormous benefits beyond those usually considered that flowed directly from production. Similarly, after the slavery era, exclusion and discrimination allowed millions of Americans and immigrants to enter occupations with greater prospects. In these ways, racism generated income and wealth that flow to present-day recipients. That is an important reality, and its consequences can be measured. The information will be salutary for all concerned, and it will focus policy discussion on constructive remedies. That leads to the “so what?” question: What difference will this information make? What practical value will restitution theory have? Managing overall national economic performance requires that policymakers understand the concept of unjust enrichment and the restitution theory. Economic underperformance is caused in part by the alienation of millions of people who believe they are victims of injustice, and withhold their best efforts in response.

All these differential practices produce a diversion of income and wealth in the United States from blacks to whites. All of them made whites better off relative to blacks, in the aggregate, than they otherwise would have been in a society, and in markets, using free and openly competitive selection processes.

The total consequence of these direct and indirect, active and passive methods of diverting income and wealth interracially resulted in unjust enrichment that can be measured. The information will be salutary for all concerned, and it will focus policy discussion on constructive remedies. That leads to the “so what?” question: What difference will this information make? What practical value will restitution theory have? Managing overall national economic performance requires that policymakers understand the concept of unjust enrichment and the restitution theory. Economic underperformance is caused in part by the alienation of millions of people who believe they are victims of injustice, and withhold their best efforts in response.

Systemic economic arrangements often are imposed by dominant social groups on less powerful ones. Invariably, these patterns of transactions produce costs for the latter and benefits for the former. Economic injustices, sustained over time, produce cumulative benefits—that is,
unjust enrichment. This can be measured. When such cumulative benefits are measured, the results can then be introduced into public policy discussions for the purpose of acknowledging the transgressions, admitting the consequences, and accepting the fact that remedies are proper, feasible, and just.

Restitution theory offers a basis for correcting the lopsided results of distortions in markets characterized by coercion, exclusion, and discrimination. It raises the prospect that the simple fact of illuminating economic relationships this way will, in and of itself, tend to reduce the offending behavior. That is because a major reason the injustices occurred in the first place, and then perpetuated, was that a veil of ignorance rested over the phenomena. Restitution theory lifts that veil, and will make it harder in the future for economic injustices to become systemic. Such injustices rely on the fact that their magnitude is not understood. Once their magnitude is discovered, political and social forces will mobilize to stop the practices and to retrieve the unjust enrichments that have been produced.

RETAIATATION

Retaliation historically refers to a legal provision that punishes the perpetrator of physical injury, whether committed as a deliberate act or through negligence, in exact conformity to the type and amount of damage that was inflicted. In a broader sense, retaliation refers to a system of justice in which the measure of payback for harms done (not just physical harms) is stated in law and recognized as equivalent punishment or compensation. In some modern contexts, retaliation for inflicting injury, quite broadly conceived, continues in use but with an extended application.

First attested in the laws of Hammurabi from ancient Babylonia c. 1750 BCE, the law of retaliation is undoubtedly best known in the form of the biblical injunction “an eye for an eye, a tooth for a tooth” (Exod. 21:23–25; similarly, Lev. 24:17–21). This provision is also known in Roman legal terminology as lex talionis (Latin talion is at the root of English “retaliation”), although Roman law (Table VIII. 2, c. 450 BCE) permitted pecuniary compensation in the place of literal retaliation. It has been argued that compensation as an alternative means of satisfaction reflects an evolution of customary practices that dealt with the inadequacy of literal retaliation, namely, the potential to increase the number of physically maimed persons in society. Although compensation became the explicit norm in Roman, Jewish and medieval law, there also is evidence for it in the laws of Hammurabi (for example, laws ¶¶ 203–204), and it dominates the relevant sections of the laws of Eshnunna (laws ¶¶ 42–48, 55–57), Babylonian laws only slightly earlier than Hammurabi. It is likely that compensation, either set by law or negotiated between the relevant parties, was always an option available to the injured party.

The purpose of laws of retaliation originally may have been to curtail excessive vengeance by or on behalf of a wronged party that would have provoked a spiral of retaliatory attacks. These laws set a just balance: an eye for an eye, or compensation determined to be equivalent. Additionally, the law may have been meant to deter prospective perpetrators by drawing attention to the personal cost of actions that cause injury. Literal retaliation prompts you to value my eye (or other body part, or life, or child, or whatever) as much as you value your own. If you would not deliberately remove your own eye, then do not deliberately remove mine, else I demand yours of you; and as you would guard against negligently losing your own eye, so you should equally guard against negligently losing mine, else I demand yours of you.

In ancient and medieval societies justice was usually not impartial; it graded punishments and compensation according to the social statuses of the perpetrator and the victim. So, for example, in the laws of Hammurabi, if an awilu (a high-status person) blinded the eye of a fellow awilu, then the penalty was the blinding of his own eye. However, if he blinded the eye of a commoner, then fixed monetary compensation was paid. Should an awilu blind the eye of a slave, a lesser fixed monetary compensation
was due, apparently to the slave owner (laws ¶¶ 196, 198–199; compare Exod. 21:26, where the blinded slave is allowed to go free, thus compensating the slave, but in common with Hammurabi, the higher-status perpetrator is not blinded). Laws of retaliation reflected and served to reinforce status distinctions in society, and thus protected the honor of high-status individuals. Certain individuals, their family members, their body parts, and their pain, were simply worth more than lower-status individuals under the law.

The developing polity, as a law-making body, assumed the role earlier performed by the extended kin group to regulate retaliatory punishments and to maintain the social status–honor regime. In modern western law, tort law regulated by the state-appointed courts has replaced retaliation, and covers a myriad of “injuries” for which one can seek redress, although the determination of just pecuniary compensation that dominates tort law obviously has roots in its ancient and medieval counterpart. “Retaliation” still features in current U.S. law in respect to employment. “Unlawful retaliation” pertains to actions taken by an employer that discriminate against an employee under the provisions of Title VII of the Civil Rights Act of 1964. If, for example, an employee makes a claim or supports the claim of a fellow worker in respect to discrimination or harassment in the workplace based on the Civil Rights Act, the employer cannot retaliate against the employee to materially adversely affect the employee in terms or conditions of employment (section 704(a) of Title VII). The Supreme Court’s 2006 decision in Burlington Northern and Santa Fe Railway v. White has significantly lowered the standard claimants must prove to win a retaliation claim. If proven to have retaliated, the employer is liable to pay a court-determined amount in compensation to the harmed employee.

Although laws of retaliation, and tort law generally, focus on individuals, the concept of retaliation has found a distinctively communal application in certain modern contexts. In international relations, for example, the nuclear arms race between the United States and the Soviet Union during the cold war moved the superpowers toward mutually assured destruction. Each developed the capability to destroy the other by launching a retaliatory strike after absorbing a first strike. Nuclear deterrence theory was predicated on the notion that the credible prospect of retaliation should act as a deterrent to a prospective perpetrator.

A second area featuring a communal conception of retaliation is international trade. In this context, trade protection by one nation can issue in trade retaliation by a trading partner, sanctioned by an international body such as the World Trade Organization (WTO). The retaliation might be of a literal kind: a tariff imposed on some good(s) to counteract a tariff imposed by the trading partner, and according to the WTO Dispute Settlement Understanding, the countermeasures should be “equivalent to the level of nullification and impairment” (Article 22.4). That is, the penalty should justly balance the infringement. The point of the retaliation is only partly to obtain compensation for the financial harm caused by protectionist policies of a trading partner. It actually seeks to pressure the protectionist trader to abandon its practices and comply with its WTO commitments. Here retaliation serves mainly as a mechanism to get a party to modify its behavior, but it also serves to warn potential perpetrators because there is a sanctioned retaliatory response.

RETURNS

The idea of returns has a long history in economics. This is not surprising because the concept of a "return" is just the flip side of the concept of cost. Accordingly we may define a return as a change in output (or the cost of producing an additional unit of output) resulting from a change in the quantity of quality of inputs. Adam Smith's famous pin factory discussion of the division of labor in the opening pages of An Inquiry into the Nature and Causes of the Wealth of Nations (1776) regards the declining costs associated with productivity-enhancing technical change. David Ricardo, in both the Essay on Profits (1815) and Of the Principles of Political Economy and Taxation (1817), described the diminishing returns associated with economic growth. Capital accumulation would lead to higher population, increasing the demand for food and thus the need to intensify and extend agricultural production. Intensification of production and the extending of production on to lands of inferior quality or further from the central markets (and thus associated with higher transportation costs) would lead to higher rents and wages, squeezing profits and choking off accumulation.

In economics the distinction must be made between returns to scale and returns to substitution. Returns to scale regards the changes in output resulting from increases in all factors of production (land, labor, and capital). For example, when all inputs are doubled: If output more than doubles, there are increasing returns to scale; if output exactly doubles, there are constant returns to scale; and if output less than doubles, there are decreasing returns to scale. Returns to substitution regards the impact of changing the quantity of one factor of production when one or more other factors are fixed in quantity. For example, when there is an increase in one input, holding the quantity of all other inputs constant: If the cost of producing an additional unit of output falls, there are increasing returns; if the cost of producing an additional unit of output stays constant, there are constant returns; if the cost of producing an additional unit of output rises, there are diminishing returns. There is no such thing as "decreasing returns to scale." If all factors are variable, then they can be combined in the proportions that produce the highest productivity and lowest costs and then replicated. There is no such thing as "increasing returns to substitution," as producers will always use the proportions that give them the lowest cost and highest productivity, even if that means not using the entire quantity of some of a resource.

Piero Sraffa (1925, 1926) showed that the neoclassical versions of nonproportional returns embodied in the U-shaped average cost curve—a necessary component of determining the equilibrium size of the firm in a perfectly competitive market—are indeed problematic. First, the two kinds of nonproportional returns—increasing and diminishing—refer to different parts of economic theory. Increasing returns is part of the theory of general economic progress and so the theory of production, while diminishing returns is part of the theory of rent and so the theory of distribution. Second, in Alfred Marshall’s framework, these must be compatible with the ceteris paribus conditions of the partial equilibrium framework while still not violating the assumptions of perfect competition (Marshall 1961). Sraffa shows this to be either terribly unrealistic or logically impossible.

In the case of diminishing returns, unless we find an industry where all firms use a scarce factor, variations in average cost associated with increased production in the industry under consideration will be of the same order of magnitude as variations in costs experienced by other industries using the same scarce factor. This violates the ceteris paribus assumption of partial equilibrium analysis. As for increasing returns, these cannot be present at the same time in both an industry and the firms within it, because otherwise firms will keep on expanding until they reach a size incompatible with perfect competition. Nor can they be found in various industries at the same time, or ceteris paribus conditions will be breached again. Marshall, aware of this, developed a category of economies of production external to the individual firm but internal to the industry. This may be proper in terms of perfect competition and partial equilibrium but wholly unrealistic.

Sraffa’s conclusion that we may find some use in the “old classical” conception of constant costs may help in theoretical models, but this does not mean that he did not acknowledge the importance of economies of scale and increasing returns in the real economy. Allyn Young (1928) just a few years later went back to Smith’s discussion of the division of labor and drew out its contemporary relevance for economic growth. One of Young’s students at the London School of Economics, Nicholas Kaldor, combined the Smith-Young insight into the mutually reinforcing relation between economic growth and technical progress and wed it to a dynamic version of John Maynard Keynes’s principle of effective demand in his notion of cumulative causation (Kaldor 1972). This analysis resulted in Kaldor’s “polarization thesis” regarding the division of the global economy into rich, industrialized nations and poor, developing national economies, which has links to the Prebisch-Singer hypothesis of declining terms of trade between the two sets of countries (Prebisch 1950; Singer 1950). Even in Smith there is the asymmetric analysis of manufactures and
Returns, Diminishing

agriculture, the former characterized by increasing returns and the latter by diminishing returns. This was abandoned by Marshall, whose model portrays all factors of production symmetrically, experiencing increasing returns as production begins and diminishing returns as production continues (as in the U-shaped average cost curve). Marshall also abandoned the qualitative aspects of returns, limiting the causes to quantitative differences only. Thus the important distinction between the classical and neoclassical notions of returns.

RETURNS, DIMINISHING

The French economist Anne-Robert-Jacques Turgot (1727–1781) is credited with introducing the concept of diminishing returns into economics. In production theory, it refers to the changes in output associated with changes in some inputs, called variable factors, while other inputs, called fixed factors, are held constant. The relation is stated as a law: with given production techniques, the increment to output associated with each additional unit of a variable factor applied to a given amount of a fixed factor will eventually diminish, which is why it is more properly called the Law of Eventually Diminishing Returns.

The short-run concept of diminishing returns is not to be confused with the long-run concept of returns to scale. The latter refers to changes in output when all inputs are altered in equal proportion. Diminishing returns caused by a hidden fixed factor has, however, been offered as one explanation of the observation of what appears to be diminishing returns to scale.

Diminishing returns provides a possible explanation of the eventual positive slope of cost curves in the short run (defined as a situation in which at least one key input is fixed). However, its most famous application was made in 1798 by the English economist Thomas Robert Malthus, who argued that increased population (and capital) applied to the given amount of a nation’s land would eventually encounter diminishing returns. Each new person added to the labor force would then add less and less to total production, until living standards are reduced to the subsistence level. It is non-controversial that, if techniques of production remain constant, increases in population (and all other inputs) with land held constant, must encounter diminishing returns to agricultural output and, hence, cause falling living standards. Malthus also noted that, if unchecked, populations tend to grow at a geometric progression. He then added the arbitrary assumption that the growth of productivity, due to the development of new technologies, would follow an arithmetic progression, which researchers today know to be incorrect.

This theory produced two famous predictions. First, the growth of population and capital would eventually lead to continually falling living standards until bare subsistence is reached. Second, the growth of capital alone could raise living standards but at a falling rate (due to diminishing returns) until the arrival of the “stationary state” in which per capita income could not be raised further. These predictions led the Scottish historian Thomas Carlyle (1795–1881) to label economics “the dismal science.”

A related concept, called diminishing returns to income, is used in the economic theory of consumption. It holds that successive increments of income give decreasing amounts of satisfaction (what economists call utility) since people’s most pressing needs will be satisfied first and then as income rises further, along with the consumption that it permits, successively less and less pressing needs will be met. The concept was long regarded as an untested although plausible hypothesis. Research summa-
rized by Richard Layard in 2005 has, however, succeeded in measuring satisfaction and has largely confirmed the hypothesis of diminishing returns to consumption—although not necessarily that of diminishing returns to income, since income may serve other purposes than permitting consumption, such as conferring power and prestige.

Physical diminishing returns is often appealed to by those who believe that sustained growth is impossible. They argue that when variable amounts of human capital and effort are applied to the world's fixed amount of resources, diminishing returns must sooner or later be encountered, slowing and eventually halting growth. Modern students of the accumulation of knowledge, and the technological change that it allows, argue otherwise. They make two points. First, unlike most economic entities that are rivalrous—if one person uses a machine, another person cannot simultaneously use it—knowledge is nonrivalrous—if one invents a new technology, everyone can use that knowledge simultaneously. Second, there is no reason to believe that the accumulation of knowledge will encounter diminishing returns when acting through the new technologies that it enables. New knowledge occasionally generates new general purpose technologies (GPTs) such as the steam engine, electricity, and the computer. These in turn make possible a massive set of derivate technological applications. There is no law in physics or economics that suggests that the power of successive GPTs to generate derivate innovations will lessen over time. Indeed, it is clear that the dynamo brought with it a much richer implied research program than did the steam engine.

Knowledge accumulation is the historical process that has allowed humanity to overcome diminishing returns through the invention of new technologies, which have enabled bursts of economic growth throughout history. The accelerating creation of new technological knowledge since the first industrial revolution may well permit the circumvention of diminishing returns by being the source of sustainable improvements in living standards in the foreseeable future.

RETURNS, INCREASING
A firm or an industry, having a given technology, exhibits increasing returns to scale if an increase in the inputs it uses to produce a particular product increases its output more than proportionately. This effect is evidenced in a decreasing long-run average cost curve. While the increasing returns concept has relevance for both microeconomics and contemporary growth theory, historically it dates from Adam Smith's Wealth of Nations (1776), which links the cost experiences of manufacturing firms to the division of labor (Smith 1776, Book I, Chapter 3). The practice leads to specialization and therefore the capability among those who specialize to trade their surpluses, which has the effect of expanding the market. Under perfect competition, declining cost has the effect of reducing selling prices. Although it reduces profits, it increases the real incomes of all classes.

Antoine Augustin Cournot, a French mathematician, was the first among several thinkers to note that increasing returns to scale are incompatible with price-taking behavior by competitive firms (Cournot 1838, pp. 59–60). A decade later, John Stuart Mill also became cognizant that economies of scale could compromise competitive markets. This possibility was, however, categorically negated by Alfred Marshall, who rejected the idea that increasing returns to scale characteristically cause industries to become monopolized. He invented external economies in the form of "general improvements," which are equally available to all firms in the industrial environment and were believed to account for the already observable tendency in the England of his day to explain declining commodity prices. Economies that are internal to firms are self-limiting, Marshall believed, partly because the full effects of economies of scale are likely to be impeded because over time "the guidance of business falls into the hands of people with less energy and less creative genius" (Marshall 1890, p. 316). Thus, Marshall maintained that monopolistic tendencies would be curbed, and competition would continue to prevail, rendering
unfounded Mill’s fear that increasing returns to scale would compromise pure competition; that is, firms and industries invariably produce under conditions of increasing supply price, which explains the upward slope of the industry supply curve.

The definitive theoretical challenge to Marshall’s conclusion that increasing returns to scale are compatible with ongoing pure competition was articulated by Piero Sraffa, who maintained that the economies needed to satisfy Marshall’s logic “were nowhere to be found” (1926, p. 540). Marshall’s particular equilibrium analysis was designed to explain price determination in a competitive industry that is identifiable in terms of the cost curves of its “representative firm.” These cost curves must be independent of those of all other firms in the industry and the industry’s factor suppliers. Thus, economies that are external to the representative firm but internal to the industry of which it is a part, which is a requirement of the particular equilibrium method, are incompatible with Marshall’s methodology. If these economies exist at all, they are “in the middle where nothing or almost nothing is to be found” because Marshall’s explanation of increasing returns is methodologically inconsistent (Sraffa 1926, p. 542). Sraffa recommended that economists give up trying to explain competitive prices and turn their attention instead to explaining prices under imperfect competition. Shortly afterward this became the objective of Joan Robinson (1933) and Edward Chamberlin (1933).

More recently, Marshall’s concept of increasing returns to scale has been “rediscovered” by contemporary “new growth” theorists (Romer 1986, 1987), who have taken the “internal-external economies” construct out of its original particular equilibrium setting in which it was intended to explain competitive price determination. They have placed it into a Walrasian general equilibrium context in which the prices of all commodity and factor markets are interdependent. The premise of the model is that the external effects of knowledge and capital accumulation can amend the Cobb-Douglas production function by a multiplicative factor to generate endogenous growth in the affected economies. It is ironic that the theoretical problem that Sraffa identified as being associated with Alfred Marshall’s concept of external economies to explain the compatibility of increasing returns and competitive equilibrium has been revived within a general equilibrium framework that is clearly incompatible with the cost-independence requirement of Marshall’s particular equilibrium analysis.

By the mid-1920s, with the assembly-line production of automobiles and other industrial products already a fact of life, a trend toward oligopoly—that is, competition among the few—was already apparent. Shortly afterward, the advent of the theories of “imperfect” and “monopolistic” competition (Robinson 1933; Chamberlin 1933) challenged the predominance of pure competition on the premise that product demand curves had come to exhibit a downward slope because firms engaged in differentiating their output had become able to charge prices in excess of the competitive “law of one price.” While they were not monopolists of their own commodities, they were able to establish demand curves for their particular brands that were less price elastic than would be the case in competitive markets in which product homogeneity assured that buyers had no basis for preferring one seller’s product over another. More recently, despite the institutional and theoretical relevance of the theory of imperfect and monopolistic competition, many thinkers maintained that economies of scale could be theoretically reconciled with perfect competition. A case in point is the interpretation by contemporary trade theorists. Helpman and Krugman (1985) argue that increasing returns might prevail as an external effect that can generate economic growth as an endogenous phenomenon and thus preserve Marshallian perfect competition.

The most forward-looking post-Marshallian interpretation about the relationship between increasing returns and market competition came from Allyn Young’s return to Smith’s theme of division of labor. In his presidential address to the British Association for the Advancement of Science, “Increasing Returns and Economic Progress,” Young noted “the most important single factor in determining the effectiveness of its industry appears to be the size of its market” (1928, p. 122) and whether it is sufficiently large to generate increasing returns. Except for the impetus that comes from new knowledge, economic progress is principally generated by division of labor to realize more fully the economies of capitalistic or round-about methods of production. Thus, Young’s “Increasing Returns” paper specifically separated Marshall’s increasing returns concept from its particular (i.e., microeconomic) industry setting and, following Smith, extended increasing returns to the economy as a whole. Thus, Young anticipated the role of Keynes’s emphasis on aggregate demand and Nicholas Kaldor’s theory of increasing returns in the process of economic growth. Yet it is only comparatively recently that Young’s special insight into the process of growth as “self perpetuating, rather than self-exhausting” has been recognized (Blitch 1983; Sandilands 2000; Rima 2004).

BIBLIOGRAPHY

The return to a fixed factor is the payment to owners of fixed inputs. This return is related to the concept of economic rent, described by the English economist David Ricardo (1772–1823) in *Principles of Political Economy and Taxation* (1817) and defined as the payment in excess of the minimum required to elicit the supply of an input in the long run. Rent is like a windfall gain and can arise because of a factor’s overall scarcity, but may also be due to differential quality, location, or other desirable characteristics of particular units of the input, as shown by R. Quentin Grafton et al. in *The Economics of the Environment and Natural Resources* (2004, pp. 215–216).

If demand exceeds current supply at the existing price, an input’s price will be bid up, thereby attracting a greater supply in the future. The larger the excess demand and the slower the supply response to a price increase, the greater will be the amount a firm has to pay for an input. Thus a factor fixed in supply, all else equal, will accrue greater returns per unit than if its supply were highly responsive to price changes. Similarly, if a factor is fixed because of inflexibilities in the production process, then any price increase imposes a greater cost burden than if the short-run use of the input could be varied.

Returns to fixed factors have a major influence on the world economy. For example, due to excess demand, the price of crude oil more than doubled over the period 2002 to 2005, despite an increase in supply. Because oil is an essential input into many production processes, firms have, in the short run, little choice but to pay the higher prices in order to maintain their production. The beneficiaries of these price hikes are oil producers. By providing a factor that has few substitutes in many production processes and is also, more or less, globally fixed in supply, rent is like a windfall gain. These surpluses are worth hundreds of billions of dollars each year and affect the standards of living of millions of people. High oil prices, in turn, encourage oil exploration that should increase supply in the future and also provide incentives for firms to modify their input mix and become less reliant on oil.

**RETURNS TO A FIXED FACTOR**

A factor of production is any input that contributes in a positive way to a production process. For example, to grow wheat a farmer requires inputs such as seed, farm machinery, land, and labor. Economists aggregate factors into three categories: (1) *land* or *natural capital* (such as soil, the air individuals breathe, or the fish in the sea); (2) *labor* (the skills people have and their education, the hours they work and how they cooperate and interact with each other); and (3) *capital* (machinery and tools that can be used to produce other goods).

An input that can only be changed in a production process in the long run is called a fixed factor. A factor may be fixed because: (1) the input might take a long time to build or replace; (2) it has few substitutes and is required in fixed proportion to other inputs; or (3) more cannot be purchased because its supply is fixed in the short run.

RETURNS TO SCALE

Returns to scale are defined as the relation between an equi-proportionate change in all the inputs used in a commodity’s production and the resulting proportionate change in the output of that commodity. The three possibilities are labeled “decreasing,” “constant,” or “increasing returns,” depending on whether a given proportionate change in all inputs causes a less than proportionate, a proportionate, or a more than proportionate change in output. Although economists debate what generates these effects, all three types are used in microeconomic theory. The common assumption in neoclassical macroeconomics is that gross domestic product (GDP) behaves as if it were generated by an aggregate production function obeying constant returns to scale.

While commonly used in economics, the concept is also used in many of the social and physical sciences. For example, in 1986 Nathan Rosenberg and L. E. Birdzell noted that the invention of the three masted sailing ship allowed Europeans to build larger ships exploiting increasing returns to scale, such as carrying capacity increasing more than in proportion to the increase in materials for construction. In 1991 Leonard Dudley analyzed military returns to scale. Some technologies, such as stone-age weapons, entailed constant returns (a larger army could expect casualties equal to those of a smaller opponent), while others, such as bronze weapons, entailed increasing returns (a larger army could expect fewer casualties than a smaller opponent). Other applications of the concept include the analysis of networks, social organization, governance, and technological change.

Mainstream micro-economists typically argue that constant returns to scale, and hence horizontal long run average cost curves, are ubiquitous given complete divisibility of all inputs. The argument is in two parts. First, decreasing returns are ruled out because it is assumed that all production activities can be replicated, for example, by building a series of identical factories, identically run and managed. Second, increasing returns are ruled out by the proportionality postulate, which states that in the absence of indivisible inputs or hidden fixed factors, any activity can be subdivided so that an equi-proportionate reduction in all inputs yield the same percentage reduction in output. Thus, if there were increasing returns to scale, the larger scale of activities could be achieved and then subdivided, leaving inputs per unit of output unchanged.

The commonly assumed U-shaped long run average cost curve for a firm, with its single most efficient scale of output, is then explained in two parts. First, the falling part (increasing returns to scale) is due to such things as indivisibilities (or “lumpiness”) in some inputs so that too much must be used at small scales of output. The rising portion (decreasing returns) is usually explained rather weakly by such things as diseconomies of management in coordinating the activities of many separate production units.

An alternative view, implicit in the work of the nineteenth-century Austrian capital theorists such as Eugene von Böhm-Bawerk and Knut Wicksell, is that returns to scale are latent in the superior productive power of indirect or intermediate production processes that create capital goods. In the twentieth century, scholars B. Curtis Eaton and Richard G. Lipsey examined this theme, providing a proof by contradiction of the existence of latent returns to scale. Lipsey, Kenneth Carlaw, and Clifford Bekar develop this further in 2005. In their research, they maintained that the standard abstract argument for constant returns to scale based on replication and the proportionality postulate is scholastic in purporting to deduce empirical relations from a priori considerations. They argued that checking the hypothesis of the ubiquitous possibility of replication requires an appeal to empirical evidence. For example, replication may not be possible if more output is required at a point in space, such as building a larger bridge over a narrows or applying more pumping power at the pit head of a coal mine. They observed that “… if the list of possible missing inputs is defined as anything that might cause the neoclassical production function to display decreasing returns, such as climate, spatial conditions of production … and a host of other unspecified influences, the proposition becomes tautological and hence uninteresting empirically” (Lipsey et al., p. 399).

Lipsey and colleagues argued similarly with respect to the proportionality postulate. If, for example, one wishes to halve the horsepower of some automobile, a smaller engine is needed. But neither “subdividing” by halving the engine’s dimensions, nor by halving all the inputs that make it, will halve the engine’s power output. Physics shows that halving its dimensions alters its cost of production, the power delivered, and running costs in different proportions, while halving all the inputs is technically inefficient because of the different dimensionality of the various components. They further argued, “‘[h]istorical increasing returns’ [to scale] arise because the scale effects are permanently embedded in the geometry and physical nature of the world in which we live, but our ability to exploit them is dependent on the existing state of technology” (Lipsey et al., p. 397).

Increasing returns to scale also arise from complementarity among components of capital and the risk of breakdown, and decreasing returns from the time cost associated with waiting to extract the service flow from durable capital goods. In all of these cases, the relationship between indivisibilities and returns to scale is the reverse of the mainstream view. Indivisibilities—building capital goods with more capacity than the minimum possible—
are the consequence of endogenous decisions to exploit naturally occurring scale effects, whereas in the mainstream view, exogenous indivisibilities are the cause of scale effects.

RETURNS TO SCALE, ASYMMETRIC

The forces which make for Increasing Return are not of the same order as those that make for Diminishing Return: and there are undoubtedly cases in which it is better to emphasize this difference by describing causes rather than results. 

(Marshall 1890, p. 266)

Asymmetric returns to scale are defined in three ways in economics. The first is the one referred to in the above quote, which is an asymmetry among increasing, constant, and decreasing returns to scale that may exist because decreasing returns to scale are thought by many to be implausible if the theoretical exercise concerning returns to scale is conducted properly. Therefore, there may be no symmetric counterpart to the increasing returns portion of production so that long run average cost curves are not symmetrically U-shaped. (Notice that the existence of decreasing returns does not necessarily imply exact symmetry in the shape of the cost curve and so this concept defined in this way is perhaps inappropriately labeled.) The a priori argument for the lack of decreasing returns is that observed apparent decreasing returns to scale actually depends on the existence of a hidden or fixed factor such as managerial or entrepreneurial capacity so that the required scaling of all factors is not actually occurring.

One counterargument to the existence of asymmetry under the first definition was provided in 2004 by Kenneth Carlaw. In his work Carlaw showed that scale effects result from the complementarities among components that make up capital goods and the risk associated with how long each component will last. The cost minimizing agent will create more durability of components than is needed for one period’s final production in order to exploit the scale effects inherent in the nature of multiple component systems and environmental uncertainty. However, at some point decreasing returns to scale set in for the durability of the capital good that is obtained from the scaling up of the durability of its components. Thus in such cases returns to scale are symmetric in the sense that increasing and then decreasing returns to scale are encountered as production with multicomponent capital goods is scaled up.

In 2005 Richard Lipsey, Kenneth Carlaw, and Clifford Bekar introduced another argument justifying the existence of diminishing returns to scale: Because real world production takes place in spatial contexts duplication may not always be possible. When and where it is possible must then be determined on empirical not a priori grounds.

A second definition of asymmetric returns to scale is that they are encountered when new technologies are applied in varying contexts. The same technology may be applied in a variety of different production, market, and institutional contexts as it emerges and is diffused across different economies. For example, lean or “just-in-time” production applied in North America is generating lower returns than in China. One suggested reason is that China has no pre-existing manufacturing infrastructure and managerial orthodoxy, whereas North American manufacturing has a solidified structure that has evolved out of the technology of mass production. It is therefore not a good fit for lean production techniques and is generating lower returns.

A third definition of asymmetric returns to scale is found in the arguments of Nicholas Kaldor. His view is
that asymmetry in the returns to scale encountered in developed and developing economies arise because of differences in the goods they produce. The comparative advantage of developing economies leads them to specialize in production technologies that have decreasing returns to scale (e.g., agriculture) while developed economies specialize in technologies that have increasing returns to scale (e.g., manufacturing).

**REVEALED PREFERENCE**

The theory of revealed preference was originally developed by Paul Samuelson using choice as a primitive to derive some fundamental principles of demand theory. In contrast, in the traditional framework of utility theory approach, the weak preference ordering of a chooser is the primitive. The motivation was that an observer does not know or observe a chooser’s preferences, but a bundle of goods a consumer buys is observable. Put differently, Samuelson’s objective was to derive the laws of demand from assumptions regarding price-quantity data without getting into any traces of preferences. The basic approach is based on the notion that in a given price-income situation, a chooser has an affordable set of consumption bundles, the budget set, and if a consumer chooses a particular bundle over all alternative bundles in the budget set, then this choice is revealed to be the chooser’s underlying preference.

This revealed preference is not necessarily the true preference of the chooser. Rather, it is the chooser’s “as if” preference. Suppose for a price-income situation \((p, M)\), \(B(p, M)\) is the budget set. A demand function is a rule that specifies exactly one element of \(B(p, M)\) for every budget set \(B(p, M)\). If both \(x\) and \(y\) are in \(B(p, M)\), and \(x\) is chosen, then \(x\) is said to be (directly) strictly revealed preferred to \(y\). It is directly revealed preferred because both \(x\) and \(y\) are compared in a budget set \(B(p, M)\); it is strictly revealed preferred since \(x\) is chosen from a budget set while \(y\) is rejected, since demand function is single-valued.

Samuelson introduces a condition, known as the weak axiom of revealed preference (WARP), which says that if \(x\) is (directly) strictly revealed preferred to \(y\), then there is no other price-income situation (i.e., budget set) in which \(y\) will be chosen while \(x\) is available. In other words, WARP requires that if \(x\) is (directly) strictly revealed preferred to \(y\), then \(y\) cannot be (directly) strictly revealed preferred to \(x\). It can be viewed as a two-term consistency. If the demand function satisfies the WARP, then it must satisfy the property that a demand function is homogeneous of degree zero in income and prices; it exhibits the non-positivity of the own compensated price effect (i.e., the substitution effect); and for every normal good, the price effect must be nonpositive. There are additional implications of the utility theory approach to consumer behavior (namely, symmetry of the cross-substitution term) that are not implied by the WARP.

The rationalizability of the demand function in terms of weak preference orderings implies that the consumer behaves as if he or she has a weak preference ordering and, given the budget set, he or she optimizes on the basis of a realized preference ordering. Rationalizability in terms of weak preference orderings implies, but is not implied by, the WARP. So the WARP needs to be strengthened. Suppose \(x\) and \(z\) are two alternatives that never appear together in any budget set. In addition, suppose \(x\) is (directly) strictly revealed preferred to \(y\), \(y\) is (directly) strictly revealed preferred to \(u\), \(u\) is (directly) strictly revealed preferred to \(w\), and \(w\) is (directly) strictly revealed preferred to \(z\). Then we say \(x\) is indirectly strictly revealed preferred to \(z\). Strengthening the WARP from a two-term consistency requirement to a multiterm consistency—known as the strong axiom of revealed preference (SARP), which says that if \(x\) is (directly) strictly revealed preferred to \(y\), then \(y\) cannot be (directly) or indirectly strictly revealed preferred to \(x\)—it can be demonstrated that this stronger requirement is a necessary and sufficient condition for the rationalizability of a demand function in terms of weak preference orderings (Houthakker). Furthermore, the SARP, together with a continuity condition, implies the existence of a utility function that rationalizes the consumer’s revealed preferences. This establishes the logical equivalence of the revealed preference approach and the utility theory approach.

Following Samuelson’s pioneering work, the revealed preference approach was developed further in an abstract
choice theoretic framework. For any given universal set of alternatives \( X \), consider all possible nonempty subsets \([X]\) of \( X \), which is the power set of the universal set minus the empty set. Consider a well-specified family \( S \) of nonempty subsets of \( X \), i.e., \( S \) is a subset of \([X]\). A choice function is a rule, \( C(\cdot) \), which for any element \( A \) of \( S \) specifies a nonempty subset of \( A \), that is, \( C(A) \) is a subset of \( A \). Note that \( C(A) \) is not necessarily single-valued. Clearly, demand function is a special case of a choice function. Now for any \( A \) in \( S \), if \( x \) is in \( C(A) \) and \( y \) is in \( A \), then \( x \) is said to be (directly) revealed preferred to \( y \). If \( x \) and \( z \) together are not in any \( S \), and if \( x \) is (directly) revealed preferred to \( y \), \( y \) is (directly) revealed preferred to \( u \), \( u \) is (directly) revealed preferred to \( w \), and \( w \) is (directly) revealed preferred to \( z \), then \( x \) is said to be indirectly revealed preferred to \( z \).

For Samuelson, a choice function must be single-valued, and the domain \( S \) must be the convex polyhedra (or the budget triangles in a two-commodity world) since the objective is to derive the laws of demand of a competitive consumer (i.e., a price taker) from observed data. For the domain \( S = [X] \), the multiterm consistency requirement of the SARP is collapsed into a two-term consistency. Consequently, the WARP becomes equivalent to the SARP (Arrow).

Suppose a multivalued choice function is defined over any arbitrary domain \( S \), a subset of \([X]\). Marcel Richter (1966) introduces a condition, called congruence axiom, which says that if \( x \) is (directly) revealed preferred to \( y \), then \( y \) cannot be directly or indirectly revealed preferred to \( x \). This condition is necessary and sufficient for transitive rationalization of a multivalued choice function in a general domain framework. Clearly, using this general approach, the demand theory results can be derived as a special case. This generalized framework helps to analyze rational choice in a wider context, such as social choice theory, voting theory, and production analysis.

The revealed preference approach developed in two directions. Following the requirement of the preference-based approach that a weak preference relation is transitive, the revealed preference literature originally developed to focus on transitive rationalization of a choice function. For the existence of a maximum, transitivity is indeed very restrictive. A less restrictive requirement could be transitivity of strict preference relation (known as quasi-transitivity) and the least restrictive requirement could be acyclicity of strict preference relation. The WARP requires that no revealed inferior alternative of a set \( A \) can be chosen in any other set in the presence of any revealed preferred alternative in \( A \). This consistency condition can be weakened by simply requiring that no revealed inferior alternative of a set \( A \) can be chosen in any other set in the presence of some revealed preferred alternative in \( A \). This weaker requirement turns out to be a necessary and sufficient condition for quasi-transitive rationalization of a choice function. Furthermore, if one requires that no revealed inferior alternative of a set \( A \) can be chosen in any other set in the presence of some alternative in \( A \), then this condition turns out to be necessary and sufficient for (acyclic) rationalization of a choice function. These results are obtained for the domain \( S = [X] \) using Samuelsonian revealed preference approach (Bandyopadhyay and Sengupta). Following Arrow’s approach, there is a large literature on alternative characterization of various weak rationalization for the domain \( S = [X] \). The results for the domain \( S = [X] \) can also be obtained for the domain that consists with all pairs and triples in \([X]\). However, there is no complete characterization of weaker rationalization result for any arbitrary \( S \) that is a subset of \([X]\).

The other line of development is in the context of stochastic demand theory. For every price-income situation \((p,M)\), a stochastic demand function (SDF) is a rule \( d \), which, for a given budget set \( B(p,M) \), specifies exactly one probability measure \( q \) over the class of all subsets of \( B(p,M) \). Let \( q = d(p,M) \), where \( d \) is an SDF, and let \( A \) be a subset of \( B(p,M) \). Then \( q(A) \) is the probability that the bundle chosen by the consumer from \( B(p,M) \) will lie in the set \( A \). Let \( B(p,M) \) and \( B(p^*,M^*) \) be the budget sets for two price-income situations. A stochastic demand function, \( d \), satisfies the weak axiom of stochastic revealed preference (WASRP) whenever for all pairs of price-income situations, and for all subsets of the intersection of the two budget sets, \( A \), \( q(A) - q(A) \leq q(B(p,M) - B(p^*,M^*)) \), where \( q = d(p,M) \) and \( q^* = d(p^*,M^*) \). WASRP generalizes laws of demand from its deterministic environment to a stochastic environment (Bandyopadhyay, Dasgupta and Pattanaik, 1999). The rationalizability of a stochastic demand function in terms of stochastic orderings has also been established. Recently, these results are generalized further by considering a stochastic demand correspondence.

The revealed preference theory has been applied largely in the evaluation of economic index numbers and in empirical tests of consistency in consumer behavior. The WARP can be used to evaluate directly a given index number.

**BIBLIOGRAPHY**

REVENUE

A firm’s revenue is distinguished from its profit. Revenue is the total money received by the firm (“total revenue”), whereas profit is total revenue less total cost. Revenue and total revenue are usually synonyms, but the latter term is used especially to delineate total money received, as distinct from the “marginal revenue” of each unit and the “average revenue” received for all units.

Marginal revenue is a central concept in microeconomic theory (Marshall [1890] 1961). It is the change in total revenue created by a one-unit increase in the quantity sold. As long as marginal revenue is positive, increasing output will cause total revenues to increase. Mathematically, marginal revenue is the derivative of total revenue with respect to quantity. Average revenue is the money collected per unit, or total revenue divided by quantity. When all units of a firm’s output (\(q\)) are sold for the same price (\(p\)), total revenue is price multiplied by quantity, \(pq\), and both marginal and average revenue are equal to price.

A perfectly competitive firm’s marginal revenue is determined solely by price because a single firm’s chosen quantity of production has a negligible effect on the market price. When one firm in a perfectly competitive market decides to produce and sell one more unit of output, the market price does not change, and so the increase in the firm’s revenues is exactly equal to the number of dollars brought in by that extra unit: its price. The mathematics behind this intuition recognizes that in this case, the derivative of total revenue is \(d(pq)/dq = p\) because price \(p\) does not change as the firm’s output \(q\) changes.

A firm with market power wields a double-edged sword. The firm can set the price for its output, but it still must contend with a downward-sloping demand curve: Selling more output requires a decrease in price, by the “law of demand.” Because of these two effects (increasing quantity while decreasing price), marginal revenue is made up of two components. When the firm decides to produce and sell one more unit of output, (1) selling more of the good increases revenue, while (2) lowering price means that less revenue is collected on each of the units that could have been sold at the higher price. Thus marginal revenue must be less than price for a firm with market power (rather than equal to price, as in the case of perfect competition, above). The two components of revenue are, respectively, the output effect and the price effect. A mathematical analysis recognizes that price now changes as the firm’s quantity changes: The derivative \(dpq/dq = p + (dpl dq)q\). The first term is the output effect and the second term is the price effect. The price effect is negative because price falls when quantity rises, and this means that the marginal revenue of producing and selling one more unit of output is less than the price for which each unit can now be sold.

Marginal revenue is also closely related to the own-price elasticity of demand, or the responsiveness of quantity demanded to a change in price. A decrease in price when demand is “elastic” causes a greater percentage increase in quantity demanded than the percentage decrease in price—that thus revenues must increase. A decrease in price when demand is “inelastic,” in contrast, causes a smaller reaction in quantity demanded, and so revenues will fall. This is especially relevant when a firm is choosing the optimal quantity to sell and costs are fixed as the quantity sold changes: Maximizing total revenue is equivalent to maximizing profits in this case. For example, a toll-road operator should decrease price as long as the resulting increase in drivers (quantity) compensates for the loss in revenue per unit. In other words, price should be decreased as long as demand is still elastic. Total revenue (and in this case, profits) will be maximized when demand is neither elastic nor inelastic. This is also the quantity at which marginal revenue is zero.

The firm with market power thus far has been assumed to sell all units of its output for the same price; that is, it does not “price discriminate.” When the firm does price discriminate it can do so either by setting separate prices for each customer or setting separate prices for different customer groups, or by adjusting price according to each customer’s quantity purchased. Average revenue will vary as quantity changes, depending on the method of price discrimination, and so total revenue may not be simply price multiplied by total quantity. One example is a quantity discount: In this case, larger quantities will have lower average revenue than smaller quantities. Another example is when the customer must pay a fee for the right to purchase each unit (a “cover charge” or “membership fee”). Total revenue includes both this fee and the revenues collected on each unit’s sale, so average revenue (per unit sold) decreases as quantity increases.
In fact, the ability to price discriminate allows the firm with market power to reduce the negative effect that the law of demand has on marginal revenue. The firm can set a higher price for those units of output for which customers have a higher willingness to pay, and set a lower price only for those units of output for which there is a lower willingness to pay. As output increases, charging separate prices for each unit or group of units purchased mitigates the price effect. The price effect may even fall to zero. Thus, when the firm price discriminates, it can be true that marginal revenue approaches price and the economic outcome may approach that of perfect competition, except that the economic value created is reallocated toward the price discriminating firm and away from the customer. This means that a firm with market power may produce more output if it can price discriminate than if it cannot. The firm will benefit from this practice, and this advantage to society may more than outweigh the loss to the consumer.

Christopher S. Ruebeck

**REVENUE, MARGINAL**

Marginal revenue is a concept introduced into economics by neoclassical economists, especially Alfred Marshall in his *Principles of Economics* (1890). It became a central concept in discussion of market structure with the publication of Joan Robinson’s *The Economics of Imperfect Competition* and Edward Chamberlin’s *The Theory of Monopolistic Competition*, both published in 1933. Since then it has been taught in all courses in microeconomics as part of the theory of the firm.

Marginal revenue refers to the change in total revenue arising from a change in output, where the change in output can denote a rise or fall and is usually thought of as a one-unit change. More formally,

\[
MR = \frac{\text{Change in total revenue}}{\text{Change in output}} = \frac{\Delta TR}{\Delta Q}
\]

where \( MR \) denotes marginal revenue, \( TR \) denotes total revenue, and \( Q \) the level of output. \( \Delta \) is the symbol to denote “a change in.”

When used in terms of market structure, marginal revenue is related to the demand curve. The demand curve is also the average revenue curve, because it denotes the price people are willing to pay for each particular quantity. In perfect competition the demand curve is horizontal at a particular price, whereas for the typical demand curve, it is downward sloping, indicating that the quantity rises when the price falls. The relationship between marginal revenue and demand is obtained by considering the change in total revenue (\( \Delta TR \)). Because total revenue is price times quantity, then \( TR = P \cdot Q \) and \( \Delta TR = P \cdot \Delta Q + Q \cdot \Delta P \). Hence, marginal revenue can be expressed as

\[
MR = \frac{\Delta TR}{\Delta Q} = P + Q \cdot \frac{\Delta P}{\Delta Q}.
\]

Under perfect competition, the price does not change whatever the level of output, so \( \Delta P/\Delta Q = 0 \) and hence marginal revenue is equal to price, which in turn is equal to average revenue. In market structures other than perfect competition, the demand curve is downward sloping, in which case \( \Delta P/\Delta Q < 0 \), and so marginal revenue is less than price and the marginal revenue curve lies below the average revenue curve—the curve that denotes the price for any level of output.

The concept of marginal revenue is useful when it is combined with other marginal concepts, especially marginal cost, which refers to the change in total cost when output changes. More specifically, because profit is the difference between total revenue and total cost, then if marginal revenue exceeds marginal cost, profit must be increasing. Profits are falling when the reverse inequality holds. This means maximum profits can be identified when marginal revenue is equal to marginal cost. In the case of perfect competition, this also means that at the profit-maximizing output level, price is equal to marginal cost. However, under imperfect competition, monopolistic competition, and other market structures such as oligopoly, at the profit-maximizing output level, marginal revenue is below average revenue, which means price is above marginal cost (which is equal to marginal revenue). Both these results have social implications.

If price is equal to marginal cost (equal to marginal revenue), then society is paying at the margin just what it costs society to produce that final extra unit. This is the condition that holds under perfect competition. In contrast, in market structures where the demand curve is downward sloping, price is above marginal cost (which is equal to marginal revenue) at the profit-maximizing output level. Socially, this means that society is paying at the margin more than it is costing society to produce that last unit. In the case of monopoly, this leads to monopoly profits. This is not the case under monopolistic competition, where in the long run such profits can be eliminated as firms enter the industry. What can be observed from
this analysis therefore is that it is the combination of marginal concepts that is important, and marginal revenue is just one of these.

Although marginal revenue, along with other marginal concepts, is taught in most courses in microeconomics, the concept is limited. The market structures referred to above in which the concept of marginal revenue played such an important part applies only to a single product firm. In fact almost all neoclassical analysis applies to single-product firms, which are abstract entities: not only do the firms produce only one product, but there is no internal organization. It would be difficult to apply the concept of marginal revenue to a modern multiproduct multinational company. Even so, as a logical concept it can eliminate muddled thinking.

REVOLUTION

*Revolution* as applied to social change originally referred to the overturning of a government but not to changes that ushered in a new age. From the fourteenth through the seventeenth centuries, Europeans spoke of “revolutions” when one form of government gave way to another, as when a monarchy was overthrown or restored or a city-state’s government shifted between republican and aristocratic rule.

The notion of political revolutions as overturning tradition, creating a new era, and thereby bringing about progress was first used toward the end of the eighteenth century to describe the overthrow of monarchies and the founding of national republics in the United States in 1776 and France in 1789. Inspired by the intellectual movement of the Enlightenment, which aimed to make reason the arbiter of governing and social institutions, opponents of traditional authority saw these events as breaking the shackles of tradition and ushering in a new era of freedom under rationally conceived political institutions. Thomas Paine, in *The Rights of Man* (1791), referred to both the “American Revolution” and “The French Revolution” in this manner.

Since the eighteenth century, the notion of revolution as marking a major break with the past, destroying old ways, and bringing progress has been applied to numerous historical and intellectual events. Archaeologists call the prehistoric onset of agriculture the Neolithic Revolution. In economics, the shift from agricultural to industrial economies is called the Industrial Revolution. In science, major shifts in leading theories are commonly labeled scientific revolutions, such as the Darwinian Revolution or the Copernican Revolution, while the term “Scientific Revolution” is used to denote the shift from traditional natural philosophy to experimental science that occurred from the sixteenth to the eighteenth centuries. More recently, agronomists have used the term “Green Revolution” to describe the widespread adoption of high-yield grains and artificial fertilizers in East Asia. In military tactics, the introduction of stealth, satellite, and laser technologies has been labeled “the revolution in military affairs.” Almost every area of human endeavor thus has come to use the term “revolution” to mark relatively sudden, progressive change.

SOCIAL AND POLITICAL REVOLUTIONS: HISTORICAL PATTERNS

The most common use of the term *revolution* in the social sciences is to designate major, sudden changes in political regimes, especially when carried forward through mass demonstrations or popular revolts and accompanied by attacks on government officials or elites, on public or private property, or on symbols of elite status or political authority. Such events are called “political revolutions” when they alter government institutions but leave much of the economic and social structure of society intact; they are called “social revolutions” (or “great revolutions”) when they alter not only government structures but also the organization of the economy, the social hierarchy, the role of religion, and major symbols and beliefs regarding authority and national identity.

Revolutions are a form of internal political conflict, related to popular rebellions, civil wars, or coups d’état. Revolutions usually include one or more of these events; but these events, by themselves or in combination, do not constitute a revolution (or attempted revolution). What defines revolution is not merely challenges to political authority or contests for power but efforts to change a society’s major political or economic or religious institutions.
Although the term is relatively new, revolutions can be identified in history as far back as ancient Egypt, where the Old Dynasty was overthrown amid popular revolts and the pharaoh was replaced by committees of notables. In classical Greece and Rome, and in medieval European city-states, political conflicts often led to a monarchy being overthrown and replaced by a republic, or a republic being overthrown and replaced by a monarch or tyrant. Another form of revolutionary movement that arose in many parts of Europe, Asia, and Africa—from the early days of Christianity to the White Lotus rebellions in eighteenth-century China—were religiously inspired movements that sought to replace secular authorities with rule by a charismatic savior or a community of “saints.”

The distinctively modern idea of revolution that developed in the eighteenth century was to see revolutions as permanent and progressive changes in the entire social order, changes that replaced outmoded and unjust political, economic, religious, and social institutions with a new social organization based on reason. This kind of revolution has since taken several forms.

**Constitutional** revolutions sought to replace traditional monarchies or empires with republics bound by newly written rules that would limit state power, end the privileges of hereditary elites, and confer rights and responsibilities on citizens. Major examples include the American Revolution (1776); the French Revolution (1789); the Revolutions of 1848 in France, Germany, and Austria; the Turkish Revolution of 1919; the Iranian Revolution of 1905; and the Chinese Republican Revolution (1911).

**Anticolonial** revolutions aimed to end rule by foreign countries, drawing on nationalist identities to inspire resistance and the foundation of new institutions of local self-rule. In many cases, nationalist traditions were in fact newly developed by elites, and in some cases self-rule became rule by local elites rather than citizen-based democracy. Major examples include the Latin American revolutions (1808–1828), the Vietnamese (1954) and Algerian (1962) revolutions, the Indian independence movement (1949), and the Mozambique and Angolan revolutions (1974).

**Fascist** revolutions also drew on nationalist traditions but used them to mobilize mass support for the replacement of weak monarchies or republics with authoritarian regimes. Major examples include Italy (1921) and Germany (1933).

**Communist** revolutions, inspired by the historical theories of Karl Marx, aimed to overturn existing regimes and replace them with one-party states that abolished private property. They created dictatorships that destroyed economic elites “in the name of the people.” Major examples include Russia (1917), China (1949), and Cuba (1959).

**Antidictatorial** revolutions, provoked by the excessive corruption or depredations of modernizing dictatorships, aimed to create new regimes based on constitutions or one-party states. Major examples include Mexico (1911), Nicaragua (1979), and the Philippines (1976).

Some revolutions combined these features; for example, the Vietnamese revolution was anticolonial and Communist. Other revolutions were distinctive and fit none of these categories; examples include the South African anti-apartheid revolution (1994), which replaced a racially exclusive regime with a multiracial democracy, or the Iranian Islamic Revolution (1979), which replaced a modernizing dictatorship with an elected government that was overseen by nonelected religious leaders.

The last several decades have seen the emergence of yet another kind of revolution, the “people power” or “color” revolutions—so termed because popular demonstrations toppled dictators, not by mass violence, but instead by rallying huge crowds around symbols of national unity and popular opposition, which were mainly colored symbols such as yellow or orange ribbons, roses, or tulips. Examples include the Philippines (1976), Ukraine (2004), Georgia (2003), and Kyrgyzstan (2005). Other examples include the Velvet Revolution in Czechoslovakia (1989) and the Cedar Revolution in Lebanon (2005).

**SOCIAL AND POLITICAL REVOLUTIONS: CAUSES, PROCESSES, OUTCOMES**

Despite their varied nature, social and political revolutions have been generally rooted in a similar set of causes. These are: (1) a crisis of state authority, often rooted in fiscal problems, military pressures, a succession crisis, or severe corruption, though it can also reflect the rise of religious or nationalist grievances against the ruling regime; (2) major divisions among and defections by the official, military, economic, and/or religious elites of the state, weakening the state and providing leadership to the opposition; (3) economic conditions that are perceived as unjustly imposing hardships on workers or peasants, and that the state is held responsible for causing or failing to ameliorate; and (4) a broad culture of opposition, which unites different social and political groups around a set of ideologies and symbols that produce antistate coalitions among diverse groups and that justifies and encourages efforts to oppose the regime. Such a culture of opposition generally draws on both historical memories of resistance and modern ideologies that depict the injustices of the current regime. In some cases, a fifth condition is important: international conditions, alliances, or conflicts that weaken the power of the ruling regime and offer opportu-
Revolution

The presence of these conditions is rarely, if ever, created simply by the efforts of revolutionary movements. Rather, such movements create some conditions, exacerbate some conditions once they begin, and take advantage of others. In many cases, the ruling regime itself creates the conditions for revolution by blundering into military or fiscal crises, alienating elites, and forging a culture of opposition by engaging in repression of opponents that is widely seen as unjustified or excessive. Revolutions thus often arise unexpectedly, as neither states nor revolutionaries expect to create all these conditions; rather, a combination of actions by state leaders, elites, and revolutionary movements, plus shifting international or economic conditions, creates the necessary conjunction.

Once a revolution begins, the process of revolution can be long drawn out. Even where the central government collapses quickly, the conflicts that ensue among moderate and radical groups contesting for power, or between the new revolutionary state and recalcitrant regions or groups, can lead to civil war, as in France, Russia, and Mexico. It thus may be a decade or more before a stable revolutionary government is established.

Alternatively, revolutionary movements may gradually establish themselves in remote regions of the countryside, patiently winning allies and extending their zones of control, and waiting for weakness and defections from the ruling regime. In such cases, although the revolutionary regime may take years or even decades to come to power, once the central government has fallen the new regime is often battle-hardened and ready to suppress its remaining foes and quickly take control of the country. This was the pattern in the Chinese and Cuban Communist revolutions.

Where the process of revolution involves drawn-out struggles for power, such processes generally favor the rise of more extreme, radical groups. These groups are often more ruthless in attacking their enemies and better able to rouse popular support by claiming more truly to embody new national identities and to be more devoted to popular demands for rapid change. Revolutions thus typically begin with a mix of moderate and radical groups in opposition to the regime; yet in the course of struggles for control of the new revolutionary state, more extremist groups tend to win out and banish or destroy the moderate opposition. Eventually, however, the regime becomes more stable and conservative, seeking mainly to conserve its power and privileges.

In some cases, the conflict between moderates and radicals persists, leading to a "second phase" of radicalism. In this phase, radicals come to worry that the original revolutionary impetus has been lost and that current officials in the revolutionary regime have become conservative; they therefore launch a renewed set of radicalizing policy initiatives. This often takes place one or two decades or more after the onset of the revolution. Examples include the Jacksonian Revolution in the new United States, the Proletarian Revolution launched by Mao Zedong in China, the radical and nationalizing policies undertaken by Lazaro Cardenas in Mexico, and the radical foreign and nuclear policies backed by Mahmoud Ahmadinejad in modern Iran.

The process of revolutionary conflicts can thus stretch over many decades. In France one can argue that the conflicts among republicans and monarchists were not settled until the defeat of Napoleon III by Prussia in 1870, almost a century after the French Revolution had begun. In China, the conflicts among republicans, warlords, Maoist radicals, and economic moderates lasted from 1911 to at least 1989.

While the causes of political and social revolutions are basically similar, the outcomes of revolutions vary greatly. In some cases, revolutionaryaries start with, and maintain, relatively moderate and focused goals of political change. Examples include the American Revolution (1776), the Latin American Revolutions (1808–1826), and the Philippines Revolution (1996). In other cases, whether through internal or external struggles in defending their revolutionary program or through ideological inspiration, revolutionaries come to embrace a more radical program of economic and social transformation, as occurred in Russia, China, Cambodia, and Cuba.

The political nature of revolutionary regimes also varies. In some cases, revolutionary leaders have been genuinely committed to achieving democracy and guided their new regimes to that goal. Examples include the United States, South Africa, Poland, Hungary, the Czech Republic, and the Philippines. In other cases, revolutionary leaders placed a higher value on staying in power or maintaining the revolutionary regime in the face of powerful threats; in these cases revolutionary regimes swiftly moved toward one-party or personal dictatorships. Examples include France, the Soviet Union, China, Cuba, Mexico, and Algeria. In some cases, the revolutionary outcomes remained mixed and unclear for some time, as with Russia's anti-Communist revolution of 1981 (first moving toward, then away from democracy), or Nicaragua's Sandinista Revolution of 1979 (first moving away, then toward, democracy).

In sum, once begun, revolutions have a wide variety of lengthy trajectories and varied outcomes. It is rarely possible to be certain in advance what those outcomes will be; instead, domestic and international struggles to defend the revolutionary regime almost inevitably reshape it, so that eventual outcomes are more a result of continuing...
processes and struggles than of a prior plan or the conditions of the former regime.

REVOLUTIONS OF IDEAS AND RELATIONSHIPS: GLOBALIZATION, MODERNIZATION, EXPECTATIONS

Although there were many national and anticolonial revolutions in the twentieth century, these events occurred against a backdrop of general, globalizing change. Some of these changes include substantial gains in life expectancies around the world, huge rises in living standards in developed countries, and vast increases in the flow of people, goods, capital, and information across and within national boundaries.

One result of these changes has been a “revolution of rising expectations.” This refers to a major shift in how people in poor regions consider their own circumstances. In earlier times, most poor people considered how they lived in comparison to that of their parents, grandparents, and immediate neighbors. How wealthy landowners, nobles, or businessmen lived was of little concern. However, rapidly rising material wealth in developed countries, plus the flow of information and communications in the form of television, movies, CDs, and travel, have made poorer regions cognizant of the much higher living standards and the progress of democracy elsewhere in the world. This has led to a revolution of “rising expectations,” such that even poor people in developing countries now expect their governments to bring material improvements to their locale and provide access for participation.

This revolution of rising expectations can, in some circumstances, feed into political movements of rebellion and revolution as well. Where governments are perceived as actively blocking improvement, as unjustly repressing political expression or social or economic opportunities, then oppositions may mobilize for rebellion. When such states are weakened, elite defections occur, and international conditions are favorable, revolutions in ideas can fuel revolutions in politics. Thus, the age of revolutions is likely far from over.

BIBLIOGRAPHY

Skocpol, Theda. 1979. States and Social Revolutions: A Comparative Analysis of France, Russia, and China. New York: Cambridge University Press.

Jack A. Goldstone
Burma, Laos, the partitioned Vietnam, and several Middle Eastern countries industrial development based on a Soviet-style planned economy held great attraction, especially in light of the Chinese revolution—a non-Western, nonwhite, and proximate model. In the cold war context the key question was whether a developmental model based on communism or one based on capitalism best satisfied the rising expectations in those countries.

In the 1960s researchers in sociology and political science applied the concept of the revolution of rising expectations to explain not only the attractiveness of communism in many third world countries but also revolutions in general, for example, the French, American, Russian, and Mexican revolutions. In 1969 James C. Davies used those cases to illustrate his J-curve hypothesis, a formal model of the relationships among rising expectations, their level of satisfaction, and revolutionary upheavals. He proposed that revolution is likely when, after a long period of rising expectations accompanied by a parallel increase in their satisfaction, a downturn occurs. When perceptions of need satisfaction decrease but expectations continue to rise, a widening gap is created between expectations and reality. That gap eventually becomes intolerable and sets the stage for rebellion against a social system that fails to fulfill its promises.

The Cuban revolution, the communist insurgency in the Dominican Republic, and several leftist movements in Latin America were attributed to unfulfilled expectations, as was the electoral success of leftist parties such as the election of Jacobo Arbenz in Guatemala (1950) and Salvador Allende in Chile (1970). At the heart of this reasoning was the assumption that the frustration of unfulfilled expectations leads to aggressive behavior, which can be manifested in political rebellion or electoral change.

**RELATIVE DEPRIVATION**

The idea that unfulfilled expectations create unstable social and political situations is closely related to the variable of relative deprivation as an explanation of civil unrest. Relative deprivation is the perceived discrepancy in what people think they should achieve and what they do achieve. It was the animating concept for a large body of research (Gurr 1970) that attempted to explain both domestic and international civil unrest. The early successes of the civil rights movement in the 1950s had been characterized as a revolution in rising expectations among American blacks, and their perceptions of the slow pace of change during the 1960s were seen as a cause of urban riots in the United States (Geschwender 1964; Runciman 1966). Several studies showed that the most intense rioting occurred in cities where improvement of conditions for blacks had been the greatest.

Most research along these lines on both urban riots and comparative revolution or insurgencies used objective macroeconomic measures to infer deprivation, for example, rising gross national product and regional occupational patterns. However, because relative deprivation is an individual judgment, conclusive proof of its determining role requires survey or interview data to gauge respondents’ perceptions directly. Studies that did collect survey data often found that the relationship was weaker than expected (Abeles 1976; McPhail 1971) or that people were much more pragmatic about future expectations than aggregate economic data might indicate (Obershall 1968), suggesting that other variables may cause civil unrest. Also, because perceptions of relative deprivation are individual phenomena, research studies often failed to explain how individual states were translated into collective action, a key process that often was left implicit or assumed.

**LATER MODELS**

Because of inconclusive empirical proof, methodological constraints, and conceptual criticisms of this body of research, more recent social science models of civil unrest and revolutionary violence have deemphasized the idea of rising expectations, their frustration by state policies, and feelings of relative deprivation. Since the 1990s the focus has been on the structure and strength of state institutions, the mobilization capacity of aggrieved populations, and the cultural processes that channel perceptions of deprivation or injustice into collective action.

Revolutions, Latin American

REVOLUTIONS, LATIN AMERICAN

Revolutions are a relatively rare but commonly studied and vaguely understood historical phenomenon. The word *revolution* comes from the physical world and generally refers to a political rotation that replaces those in power with a previously dispossessed class of people. The term is sometimes used so loosely to refer to any palace coup or change of power that it loses all meaning. Alternatively, some historians will restrict usage to highly exceptional events, such as the 1640 English Revolution, the 1789 French Revolution, and the 1917 Bolshevik Revolution. Others contend that even those changes were not profound or permanent enough to warrant use of the term. Some assert that social changes, such as those that accompanied the Industrial Revolution, were more significant than those in the political realm where the term is commonly applied.

Likewise, Latin America scholars have not reached consensus on which events to characterize as revolutionary. Previously the term was commonly applied to early nineteenth-century anticolonial movements. Many scholars now view these as elite movements that, while resulting in political independence from European powers, also entrenched preexisting social, political, and economic structures. The one exception is the 1791 Haitian slave revolt. After ten years of sustained warfare, plantation slaves in this French colony overthrew the planter class, destroyed the sugar-based export economic system, and created a new government led largely by ex-slaves. Although rarely considered as one of the classic examples of a revolutionary movement, it was one of the deepest and most profound revolutionary changes in the history of the modern world. Some have taken its levels of brutal violence and the resulting impoverished state as a caution against attempting revolutionary changes.

Interpretations of what causes revolutionary changes, how to understand them, and how they have uniquely developed in Latin America tend to revolve around numerous themes, including the question of who is most likely to revolt. Writing in a European context, Karl Marx (1818–1883) contended that an urban proletariat would lead revolutionary changes. He considered Latin America, with its lack of an advanced industrial economy, to be not ready for a revolution. In the twentieth century, however, Latin America has perhaps experienced more revolutionary movements than any other area of the world, and these have mostly been led by the peasant classes. Revolutionaries also debated how quickly changes could be implemented, and whether violence was necessary to achieve change.

Revolutions are commonly assumed to emerge out of oppression, but Russian revolutionary Leon Trotsky (1879–1940) famously observed that if exploitation alone caused an insurrection, the masses would constantly be in revolt. Rather, as historian Crane Brinton (1898–1968) argued in *The Anatomy of Revolution* (1965), revolutions emerge out of rising expectations. Latin American events seem to underscore the need for a charismatic leader (such as Fidel Castro in Cuba) who can appeal to a coherent (and often nationalist) ideology that gains broad appeal. Anti-imperialist rhetoric and actions usually trigger strong responses from the United States. A successful revolution required the mobilization of significant organizational and material resources, both to overcome U.S. support for the previous government and to overcome opposition to the new regime. It would also appear that revolutions only succeed with the collapse of a weakened and discredited *ancien régime*. While revolution is often seen as synonymous with violence, notable examples (Chile in 1970, Venezuela in 1989) point to the potential for deep structural changes through peaceful and institutional means.

MEXICAN REVOLUTION

The 1910 Mexican Revolution is often seen as a standard bearer through which other subsequent Latin American revolutions are interpreted. Historians debate whether it was truly a social revolution, a rebellion, a civil war, or a mindless blood-letting. It began in 1910 with Francisco Madero's (1873–1913) liberal Plan of San Luis Potosí that called for free elections in the face of Porfirio Díaz's (1830–1915) seemingly entrenched thirty-five-year dictatorship. A popular uprising led Diaz to resign and leave for exile in Europe the following year, but this led to ten years of often chaotic warfare that left one million people dead. On Madero's left, Emiliano Zapata (1879–1919) and Francisco (Pancho) Villa (1878–1923) demanded deeper social and political changes. Zapata's Plan of Ayala called for agrarian reform and introduced one of the revolution's most noted slogans, “Land and Liberty.” These peasant demands, together with a wide-reaching labor code and liberal anticlerical reforms that curtailed the power of the Catholic Church, were institutionalized into
a progressive 1917 constitution. Many of these promised reforms were not realized until the 1930s under the Lázaro Cárdenas (1895–1970) government, which is best known for nationalizing the country’s petroleum reserves.

GUATEMALA

Similar to Díaz in Mexico, Guatemala’s strongly pro–United States dictator, Jorge Ubico (1878–1946), appeared to be deeply entrenched in power (1931–1944) but quickly fell when the population withdrew support. An urban middle class called for liberal reforms similar to those that Madero had championed. Educator Juan José Arévalo (1904–1990) won elections and served for five years (1945–1950), during which time he implemented moderate labor, social security, and agrarian reforms. Jacobo Arbenz (1913–1971) won the 1950 presidential elections and dramatically increased the speed of reforms. Most notably, a 1952 land reform program known as Decree 900 expropriated unused United Fruit Company (UFCO) land. In response, U.S. Secretary of State John Foster Dulles (1888–1959) and CIA director Allen Dulles (1893–1969), who both sat on the UFCO board of directors, authorized a 1954 coup that overthrew Arbenz and implemented a long and bloody military dictatorship.

MOVIMIENTO NACIONALISTA REVOLUCIONARIO (MNR)

A short insurrection on April 9 to 11, 1952, brought the Nationalist Revolutionary Movement (MNR) to power in Bolivia after leader Víctor Paz Estenssoro (1907–2001) had won the 1951 elections but the military prevented him from taking power. As in Guatemala, the MNR’s base of support was in the urban middle classes. Workers and peasants quickly exploited this political opening, and demanded more radical structural changes, including nationalization of tin mines, agrarian reform that broke up large landed estates (haciendas), and universal suffrage that eliminated literacy restrictions. This led to some of the most militant labor and peasant unions in Latin America. Notably, the MNR’s radical reforms did not trigger U.S. intervention as did Arbenz’s in Guatemala. Historians have debated these contrasting responses, with explanatory factors including Bolivia’s greater distance from the U.S. sphere of influence, domestic rather than foreign ownership of the nationalized commodities, and the MNR’s willingness to accommodate U.S. demands.

CUBAN REVOLUTION

The 1959 Cuban Revolution was the most successful, long lasting, and far-reaching of the twentieth-century revolutions. On July 26, 1953, Fidel Castro led a failed attack on the Moncada Barracks in Santiago in eastern Cuba that he hoped would spark a popular uprising against the corrupt Fulgencio Batista (1901–1973) dictatorship (1934–1959). Timed to correspond with the centennial of the birth of the independence hero José Martí (1853–1895), Castro appealed to his nationalist legacy. Castro went into exile in Mexico, where he met the Argentine Ernesto “Che” Guevara (1928–1967), who had just witnessed the coup against Arbenz in Guatemala. Guevara, who subsequently became the Americas’ most renowned guerrilla leader and theoretician, argued that revolutionary should arm the masses and not hesitate to execute their opponents. His policies assured Cuba’s survival even as the new revolutionary government’s extensive land reform program and expropriation of foreign industries led to the failed U.S.-backed Bay of Pigs invasion in 1961.

As revolutionary leaders consolidated their control over the island, they radicalized and extended reforms, often with dramatic results. Gains in education and health care led to socioeconomic indicators that rivaled those of the industrial world, sometimes surpassing those in the United States. Critics complained, however, that this was done at the cost of individual liberties. Although strong by developing world standards, Cuba failed to reach the goal of an industrialized economy.

Meanwhile, Guevara left Cuba to continue revolutionary struggles elsewhere in Latin America and Africa. He was most noted for his foco theory of guerrilla warfare that challenged traditional Marxist doctrines of waiting for proper objective conditions for a revolutionary struggle. Rather, Guevara believed that the triumph of the Cuban Revolution demonstrated that a small insurrectionary guerrilla force (the foco) could create the conditions for a revolution. A subsequent attempt to implement this theory in Bolivia in 1967 failed spectacularly and led to Guevara’s death. As a martyr, Guevara became renowned for his selfless dedication to a revolutionary struggle.

CHILEAN ROAD TO SOCIALISM

With Guevara’s defeat in Bolivia and the 1970 election of Marxist Salvador Allende (1908–1973) to the presidency in Chile, leftist sentiments swung away from searching for revolutionary changes through guerrilla struggles and toward using constitutional and institutional means. Similar to Arbenz in Guatemala, Allende came to power through constitutional means, dramatically accelerated reforms begun under his predecessor, and quickly alienated the U.S. government. His goal to transform Chile from a capitalist and dependent society into a socialist and independent one within a democratic and constitutional framework realized significant gains for the lower classes at a cost to the wealthy elite. Nationalization of U.S.-owned copper mines led, as in Guatemala, to U.S. support for Augusto Pinochet’s brutal September 11, 1973, military coup.
SANDINISTAS
With the collapse of Allende’s government, leftist sentiments swung away from the possibilities for electoral means to social revolutionary changes. Led by the Frente Sandinista para la Liberación Nacional (FSLN, Sandinista Front for National Liberation), on July 19, 1979, a guerrilla army defeated U.S.-backed dictator Anastasio Somoza (1925–1980) and took power in Nicaragua. The Somoza family dynasty had ruled the small Central American country since the 1930s. Similar to Castro’s use of Martí in Cuba, revolutionary leader Carlos Fonseca (1936–1976) appealed to the nationalist image of Augusto César Sandino (1895–1934), who had fought the U.S. Marines to a standoff in the 1930s.

In power, the Sandinistas implemented goals of a mixed economy, plural political system, and a nonaligned foreign policy. As one of the poorest countries in Latin America, Nicaragua lacked the economic significance of Chile, Cuba, or Guatemala. Nevertheless, the United States feared its independent example and helped train and arm a counter-revolutionary force (called the contras) that drug the country down and halted agrarian and social reforms. Ironically, the one lasting legacy of the Sandinistas was implementation for the first time of a functioning electoral system that opponents used to remove the revolutionaries from power in 1990. The defeat of the Sandinistas brought to an end in the minds of many proponents the possibilities for an armed path toward a socialist revolution.

ZAPATISTAS
Four years after the electoral defeat of the Sandinistas, the launch of a guerrilla war in the impoverished southern Mexican state of Chiapas caught the world by surprise. Led by a charismatic masked Subcomandante Marcos, the Ejército Zapatista de Liberación Nacional (EZLN, Zapatista Army of National Liberation) occupied five towns on January 1, 1994. They announced their opposition to neoliberal economic policies that favored the elite at a cost to the impoverished indigenous masses. The EZLN conceptualized the struggle as a continuation of that which their namesake, Emiliano Zapata, had launched at the beginning of the twentieth century. Despite sparking the imagination of leftists around the world, they made few concrete gains.

BOLIVARIAN REVOLUTION
Since elected president in 1998, Hugo Chávez has brought his uniquely styled Bolivarian Revolution to Venezuela. Chávez embodied many of the debates concerning revolutionary movements from throughout the twentieth century. After a failed 1992 coup, Chávez turned toward an electoral apparatus to gain power. Rather than contradictory or ironic, it indicates that these are simply different and not necessarily contradictory strategies in a common revolutionary struggle. As with previous revolutionaries, Chávez is a charismatic leader who provided the inspiration that drove his movement. Similar to how Castro appealed to Martí, and Fonseca to Sandino, Chávez held up Latin American independence leader Simón Bolívar (1783–1830) as his symbolic nationalist hero. Even though Venezuela is primarily an urban country, Chávez continued to emphasize and draw support from peasant and indigenous peoples. His fervent anti-imperialist rhetoric led to strong opposition from the United States, but unlike Allende he weathered an April 11, 2002, coup attempt and consolidated his hold on power. Meanwhile, Chávez’s social programs brought education and health care to the lower classes, significantly raising their standard of living. Chávez seemed not only to have learned the lessons of a century of revolutionary movements, but also to embody a synthesis of their gains.

REVOLUTIONS, SCIENTIFIC
Although the expression scientific revolution is perhaps most closely associated with Thomas Kuhn (1922–1996), who embedded the phrase in a general theory of scientific change, it also names a specific time and place—western...
Europe of the seventeenth century—from which descend the modern institutions, methods, theories, and attitudes of science, as epitomized in the achievements of such figures as Galileo (1564–1642), Francis Bacon (1561–1626), René Descartes (1596–1650), and most of all, Isaac Newton (1642–1727). That sense was only coined in the 1940s by Herbert Butterfield (1900–1979) and Kuhn's historiographical inspiration, Alexandre Koyré (1892–1964), an expatriate Russian-French philosopher influenced in equal measure by Plato (c. 427–347 BCE) and G. W. F. Hegel (1770–1831).

The use of the same phrase, scientific revolution, in its general and specific senses is only partly justified. The specific coinage was intended as provocative. It served to consign the Renaissance to a premodern past in which the scientific imagination (which Koyré understood as purely theory-driven) had been held back by the demands of secular governance and everyday life. Thus, Koyré contrasted two Italians who had been previously seen in much the same light: Galileo's single-minded pursuit of a unified truth marked him as a scientist, whereas Leonardo da Vinci's (1452–1519) jack-of-all-trades empiricism did not. The rhetorical force of this distinction was not lost in the postwar period. In the aftermath of two world wars that implicated science in the manufacture of weapons of mass destruction, the future of science required that it be seen as having revolted not only from religion but perhaps more importantly, technology.

A deeper point became more apparent with another postwar project: Joseph Needham's (1900–1995) multivolume comparative study of “science and civilization” in China. China was Europe's economic superior until the early nineteenth century, though it had never passed through a scientific revolution. Science required the belief that humans enjoy a privileged cognitive position in nature, a status associated with the great monotheistic religions descended from Judaism but not those of Asia, where humans were seen more as one with the natural world. The idea that humans might transcend—rather than simply adapt to—their natural condition so as to adopt a "god's eye point of view," especially one that would enable the "reverse engineering" of nature, was profoundly alien to the Chinese way of knowing. In this respect, the scientific revolution marked a revolt against nature itself, which was seen as not fully formed, an unrealized potential. Francis Bacon's account of experimentation famously expressed this sensibility as forcing nature to reveal her secrets, namely, possibilities that would not be encountered in the normal course of experience.

This deeper point had become widespread in the West by the late eighteenth century, especially after Newton's achievement inspired philosophers—not least those behind the American and French revolutions—to envisage society as something designed ex nihilo on the basis of a few mutually agreeable principles, what continues today as social contract theory. In this context, the precontractarian "natural" state of humanity appears unruly because its wilder animal tendencies have yet to be subject to a higher intelligence, secularly known as rationality.

The joining of political and scientific revolutions in this radical sense is due to the Marquis de Condorcet (1743–1794), who specifically connected the successful American Revolution and the ongoing French Revolution via the rhetoric of the first self-declared scientific revolutionary, Antoine Lavoisier (1743–1794). Lavoisier had recently reorganized chemistry from its traditional alchemical practices to a science founded on the systematic interrelation of elements. However, he himself was not an enthusiastic supporter of revolutionary politics, unlike his great English scientific rival, Joseph Priestley (1733–1804). Lavoisier believed that a scientific revolution could stabilize (rather than dynamize, as Priestley thought) the political order. Here Lavoisier fell back on the classical conception of revolution, suggested in the Latin etymology, as a restoration of equilibrium after some crime or societal disorder. Specifically, Lavoisier opposed Priestley's continued support for the practically useful, but logically confused, concept of phlogiston, the modern remnant of the ancient idea that fire is an ultimate constituent of nature.

Kuhn's relevance emerges at this point—and not only because his own most carefully worked out case of a scientific revolution was the dispute between Priestley and Lavoisier over the nature of oxygen. Kuhn too thought that revolutions restored stability to a science fraught with long unsolved problems. But more generally, Kuhn portrays scientists as the final arbiters of when their knowledge has sufficiently matured to be applied in society without destabilizing it. This doubly conservative conception of revolutions reflects Kuhn's definition of science as dominated by only one paradigm at any given moment. Consequently, despite Kuhn's broad cross-disciplinary appeal, especially among social scientists, he consistently maintained that only the physical sciences satisfy his strict definition because only in these fields (and arguably only until about the 1920s) are scientists in sufficient control of the research agenda to determine when and how a revolution begins and ends, and its results spread more widely.

Kuhn's conception of scientific revolutions appeared radical in the late 1960s because it was conflated with the prevalent Marxist idea of revolution as an irreversible break with the past, something closer in spirit to Condorcet's original conception. This conflation was facilitated by Kuhn's portrayal of scientists in the vanguard vis-à-vis the direction of their own work and its larger
societal import. This image was in marked contrast with the perceived captivity of scientists to what C. Wright Mills (1916–1962) called the “military-industrial complex.” However, Kuhn’s own reluctance to engage with his radical admirers suggests that his model was proposed more in the spirit of nostalgia than criticism and reform. This interpretation is supported by the original Harvard context for the restorative conception of revolution, the so-called Pareto Circle, a reading group named after the Italian political economist whose “circulation of elites” model was seen in the middle third of the twentieth century as the strongest rival to Karl Marx’s (1818–1883) theory of proletarian revolution. This group convened in the 1930s by the biochemist Lawrence Henderson (1878–1942), who taught the first history of science courses at Harvard, and who was instrumental in the appointment of chemistry department head, James Bryant Conant (1893–1978), as university president. As president, Conant hired Kuhn and coauthored the case history on the chemical revolution that launched the latter’s more generally influential thinking about scientific revolutions.

**RHETORIC**

Rhetoric is employed in both act and perception, in private thought and public communication. It is a means of communication as well as a theory for understanding and criticizing itself and the alternative means of communication. Wedded by the motives of both author and audience, the rhetoric of the social sciences is, like other rhetorics, simultaneously a guide for persuasive writing and a framework for intelligent reading. Centrally speaking, the rhetoric of the social sciences is the study and practice of argumentation and proof making, constrained only by the available means of persuasion. As such, rhetoric judges and is judged, it moves and is moved. Rhetoric is our ways and means of scientific deliberation. Following the models of Aristotle (c. 384–322 BCE) and of Cicero (106–43 BCE), the Roman statesman and philosopher, rhetoric is also importantly about the *ethos* or character of the author; to some theorists, such as Quintilian (35–96 CE), it is nothing less than “the good person speaking well.”

Rarely claimed after Aristotle to be a science unto itself, rhetoric as a discipline has profoundly shaped the sciences, and each of the sciences, including the social sciences, have returned the sometimes painful favor by reshaping and redefining the theories and vocabularies of rhetoric; (cf. Socrates, in Plato’s *Phaedrus*: “The method of the science of medicine is, I suppose, the same as the science of rhetoric. . . . In both sciences it is necessary to determine the nature of something” [2005, p. 56]).

An ancient discipline of Greek and Latin origins established originally for pleadings in law, politics, and international commerce, the rhetorical theories of Cicero, Quintilian, St. Augustine (354–430 CE), and especially Aristotle proved to be of central importance to all of human communication, including scientific communication, and became the foundation for liberal education in Europe for more than twenty centuries. The influence of rhetoric was particularly strong in the medieval university *trivium*, of which St. Thomas Aquinas (c. 1225–1274) is a product. The trivium was organized around three basic subjects: grammar (that is, words, word order, phonics, sentence structure, and the like), logic (syllogism, cause and effect, quality versus quantity, and so forth), and rhetoric—with rhetoric presiding as queen and lord. Rhetoric was not a mere synthesis of grammar and logic, though partly it was; rhetoric provided fundamental training in strategic theories of persuasion. It gave students practice in the arts of persuasion and good citizenship that would be necessary for success in later pursuits, such as immediately in the *quadrivium* (the study of mathematics, science, and music) and followed by (at least for some students) investigations in philosophy, theology, and public service. Compared to today’s four- or five-step handbooks on “valid” scientific method, the handbooks of rhetoric appear, like scientific argument itself, copious. In Aristotle’s *On Rhetoric* alone, one can identify several scores of distinct strategies for argument and proof, and literally thousands more of unique “commonplaces” (or *topoi*)—that is, general and particular sites of knowledge and belief—for use in designing arguments (Aristotle [c. 350 BCE] 1991). The sum of the permutations, a subset of all the available means of persuasion, is immense.

In the sixteenth century a Frenchman named Peter Ramus (1515–1572) was deeply inspired by his surface reading of Plato (c. 427–347 BCE), the sophists, and other classical rhetoricians. A persuasive and powerful (but not, it seems, a highly original or ethical thinker), Ramus commenced to reduce the very word *rhetoric* to mere “style,”
emotion,” “ornament,” or, in the foulest of moods, “manipulation”—a project that was encouraged by the so-called scientific revolution, of which Ramus was a part. In the century before René Descartes, Ramus thought a new language and taxonomy of thought were necessary to suit the scientific and mathematical ideas of the Renaissance, and Aristotelian rhetoric and logic, which students had been learning for centuries, was eclipsing, he said, the full reception of those ideas (Ong 1958; Olmsted 2006). That Ramus himself adapted ancient principles of rhetoric (such as the pairing of opposites) to enact his, as Ong puts it, “superficial” revolution was to Ramus and his followers apparently beside the point. The fleeting success of antirhetoric rhetoric—such as, to repeat, Ramus’s own reduction of the very word to mean “mere” style—had been observed in previous epochs, however, and would periodically recur.

In educated circles of the late eighteenth century, rhetoric reappeared in a form closer to its ancient, philosophical stature (Adam Smith and Jeremy Bentham each wrote a book on rhetoric, Smith emphasizing the rhetoric of belles lettres and Bentham the fallacies of political pundit). In the second half of the nineteenth century a notable addition to rhetoric and religion was supplied by Cardinal Newman in Essay in Aid of a Grammar of Assent (c. 1870). Rhetoric was then shoved far under the rug by neopositivists of the late nineteenth and early twentieth century (the neopositivists were a diverse group that included, among others, the scientist-philosophers Karl Pearson, Ernst Mach, and the so-called “scientific socialists”). But the logical positivists, the members and philosophical allies of the Vienna Circle, went even further and tried with some success to bury rhetoric along with other “cognitively meaningless” subjects such as, they said, metaphysics, theology, and poetry. In retrospect, the positivists said, their goal was not to kill off rhetoric and other humanistic disciplines but simply to banish them from scientific deliberation.

In the 1940s and 1950s the study of rhetoric was again revived to respectability, this time by the writings of I. A. Richards, Kenneth Burke, Richard McKeon, Chaim Perelman, Wayne Booth, Richard Weaver, and some others. A tiny postwar boom came to rhetoric by way of a delayed interest in the philosophy of Friedrich Nietzsche (1844–1900) and American philosophical pragmatism (represented by C. S. Peirce, William James, and John Dewey), both of which, like Aristotle and his followers, saw symbols and human action as inextricably entwined, even in science. A larger boost came from specific economic and cultural change. Demand for workers in the fields of technology, such as in for example the increasingly important radio and broadcast journalism industries, gave new value to the skills of the rhetorician. And in the 1970s and 1980s the philosophical and cultural movements generally referred to as “postmodernism” gave new purpose to theories and arts of communication, that is, to rhetoric.

Nowadays the larger universities maintain a department of rhetoric. If lacking a full department of their own, academic rhetoricians find employment with journalists and others in a department of communication studies, with political scientists and others in a school of public affairs, or with scientists, historians, and philosophers in the departments of classics and science and technology studies.

Rhetoric is among the oldest of subjects and also the most fluid. The fluidity of rhetoric—its ability to adapt to radically changing social, economic, and political conditions—is essential to and descriptive of its fitness. Rhetoric is constantly under attack, often by highly skilled writers. To them—the Platonists, the Ramists, the Cartesians, the logical positivists, the scientific socialists, and the media journalists—the University of Chicago philosopher Richard McKeon (1900–1985) never tired of pointing out that because rhetorical choices are always being made—from the arid symbols of first-order predicate logic to the manifestos of scientists and philosophers who would deny the force of rhetoric—rhetorical training is always relevant to the human condition.

Contemporary social scientists are formally speaking innocent of their own rhetoric. That is not to say they do not grasp the words, facts, models, theories, experimental methods, and institutional environments with which and in which they operate; rather, with a few exceptions, professional societies and the modern university do not require more than an imitative capacity to work with other than highly specific, state-of-the-art rhetorical forms to gain in-group authority (Latour and Woolgar 1979; McCloskey 1985; Nelson, Megill, McCloskey 1987; Brown 1989; Klamer 2007). A mathematical article purporting to prove with utility theory the goodness of market economies, for example, is not likely to refer to the decline of “character” talk in nineteenth-century economic psychology. Nor is the positive social scientist likely to know or even care about the purposive erasure of “ethics” and “narrative” from twentieth-century economic thought. Today’s social scientist is trained to believe with the Publication Manual of the American Psychological Association that there is only one scientific style—today’s style, exemplified by articles published in the top-ranked journals. Her neatly separated section titles—introduction, theory, model, data, hypothesis test, policy implications, conclusion—are said by her teachers to represent distinct and nonrhetorical epistemic objects (Bazerman 1988). She is trained to “let the facts speak for themselves” and to keep her values out of sight (Burke 1950; Booth 1974; Fish 1990). Likewise, the empirical economist does...
not bother to learn the rhetorical history of "statistical significance testing," even though significance testing is his lifeblood, and does not achieve the crucial "test" of "economic" or "social scientific significance" his handbook on method imagines (McCloskey and Ziliak 1996; Ziliak and McCloskey 2007). The loss of rhetoric in social science training is more than a simple academic farewell to reason.

Some observers argue that without a basic training in rhetoric, a social scientist cannot know the difference between knowledge and belief, and why the difference matters. Quite a few others think that the reason to bring rhetoric back to the center of education—including graduate education—is that highly specialized scientists would become better equipped to speak with other specialists, and, perhaps more importantly, with policy makers and the general public. Specialization, Adam Smith observed, is on balance good for society; but he added that it is only through mutually beneficial exchange that the gains from specialization can be realized ([1762–1763] 1963). Rhetoric, some say, enables both the means and the ends.

RHODES, CECIL

1853–1902

Cecil John Rhodes, a British immigrant to southern Africa, founded the De Beers diamond monopoly, served as prime minister of Britain’s Cape Colony, and colonized Southern and Northern Rhodesia (later Zimbabwe and Zambia). Rhodes was the embodiment of late nineteenth-century rapacious capitalism and imperialism. His activities did much to shape important objects of social scientific study with respect to southern Africa: monopoly capitalism, migrant labor, and colonialism.

Rhodes was born to an English parson of modest circumstances. At the age of seventeen, he emigrated to southern Africa. Rhodes arrived in 1870, three years after a diamond-mining rush had begun in an area soon to be annexed by Britain and incorporated into the Cape Colony. The following year, Rhodes left for the diamond fields, where the town of Kimberley emerged to support the mines. Diamonds quickly transformed the region’s political economy, becoming the Cape Colony’s largest export by 1875 and leading to calls for confederation of the region’s colonies and settler states.
In 1880 Rhodes and Charles Dunnell Rudd (1844–1916) formed the De Beers Mining Company to pursue amalgamation of claims, by then considered essential to continued profitability of the mines. By the end of the decade, De Beers completely controlled the diamond mines; more than a century later, De Beers remains the world’s largest miner and seller of diamonds and controls the world market in these gems. Amalgamation was intended to remedy major problems of production and marketing. First, as the mines went deeper, enormous amounts of machinery and technical expertise were needed to shore up walls and to cart ore to the surface. Though operations were capital-intensive, they were also labor-intensive, requiring increasing numbers of African men who came to the mines as migrant workers. Second, the huge volume of diamonds being produced from the Kimberley mines meant that it was necessary to limit the numbers reaching the market in order for sales to be profitable. Amalgamation enabled De Beers to solve these problems through centrally organizing flows of capital and labor into the mines and the flow of diamonds out of them. Key innovations, introduced in 1882, were closed compounds to house African workers and legislation to control illicit diamond buying. Closed compounds enabled mining concerns to closely supervise workers, bringing about tighter labor discipline and providing a model for later mining enterprises in southern Africa.

In the late-1880s, prospectors discovered the world’s largest gold deposit on the Witwatersrand (Rand) in the Boer-ruled Transvaal. The city of Johannesburg grew up above the mines, becoming the subcontinent’s largest city. Kimberley capitalists invested heavily in the Rand, but Rhodes was late to do so, securing poor claims. As a result, his interest was drawn in two directions: toward politics and toward possible mineral discoveries in areas then beyond colonial control north of the Limpopo River.

At the end of the 1880s, Rhodes’s agents fraudulently secured from Ndebele king Lobengula (c. 1836–1894) a concession (the Rudd Concession) to exploit all the minerals in his domain. On the strength of this concession, Rhodes obtained a royal charter for his British South Africa Company (BSAC) and sold shares for an enterprise to settle and mine what became Northern and Southern Rhodesia. When the areas the BSAC first exploited failed to produce a “second Rand,” the BSAC provoked war with and swiftly defeated the Ndebele. The politics of the Cape, the Transvaal, and BSAC-occupied territories to the north now became deeply entwined. Rhodes, then the Cape’s prime minister, conspired with others to topple the Transvaal government in order to install a government more conducive to mining and British imperialism. An armed force under Rhodes’s aide, Leander Starr Jameson (1853–1917), launched a hapless invasion from the north in late 1895; its failure forced Rhodes’s resigna-

tion as prime minister. Tensions over the Jameson raid helped precipitate war between Britain and the Boer republics (the Transvaal and Orange Free State). The Boer War, later known as the South African War, led to uniting South Africa as a white settler state within the British Empire. Meanwhile, oppressive BSAC policies toward Africans in Rhodesia led to a widespread uprising in 1896 to 1897 that was put down at great cost in African lives.

As he gained wealth and power, Rhodes promoted a broad imperialist vision, summed up in his scheme for a transportation network that would span Africa from the Cape to Cairo and parodied in a contemporary political cartoon that showed Rhodes astride the African continent as the “Colossus of Rhodes.” As the Cape’s prime minister, in 1894 he secured passage of the Glen Grey Act, designed to limit African access to land, force Africans onto the labor market, and reduce African voting strength. His rhetoric and actions thus place him as one of a handful of white power brokers in late nineteenth-century southern Africa who shaped the regimes of alienation of land, exploitation of minerals, and racist regimentation of labor that were to define white-ruled southern Africa for most of the twentieth century. Not yet fifty when he died, Rhodes’s will founded the Rhodes Scholarship program for anglo-saxon men from settler societies to study at Oxford University, where he had taken a degree in 1881. He is buried on a hilltop in the Matopos hills of southwestern Zimbabwe, a site sacred to indigenous peoples. His grave thus is a continual reminder of colonial conquest and insensitivity, while its broad vistas give expression to imperial desires to be master of all one surveys.

RICARDIAN EQUIVALENCE

The term *Ricardian equivalence* was coined by the American economist Robert Barro in the 1970s and sub-
 subsequently became a standard topic in public finance and macroeconomic theory. The Ricardian equivalence theorem ascribes to David Ricardo (1772–1823), the English economist, the view that taxation and public borrowing constitute equivalent forms of financing public expenditure. The rationale behind this view is that the government is expected at some future time to redeem its debt. If one now supposes a closed economy, the repayment of debt will take place via increased future taxation, which means that, on the basis of the rational expectations hypothesis, individuals increase their savings through buying the bonds that have been issued by the government. The amount of savings, in other words, matches the size of the public deficit and therefore the interest-rate remains the same. This means that there is no crowding-out effect of private investment from public expenditure and the overall demand remains the same together with the other real variables of the economy.

A similar mechanism operates in the case of an open economy, where the redemption of public debt takes place via the sale of assets to international institutional agents. Such a possibility raises, once again, the question of limited future government income, hence the inevitable future increase of taxation. Consequently, Robert Barro in the early 1970s and the new classical economists argued that either method of financing public expenditure, that is, through taxation or borrowing, leads to the same final results. The theorem has been used to argue against government intervention in the economy through fiscal policy because it suggests that the government cannot achieve anything quite different from the free operation of market forces. Monetary policy has similar effects; for example, if government expands the money supply, the public does not increase its expenditures but rather its savings in order to meet the future tax obligations. In short, Ricardian equivalence became a necessary weapon in the armory of the new classical economics in their defense of “free market.”

The truth, however, is that Ricardo, to whom this theorem is attributed, repudiated the notion of equivalence between the two ways of financing government expenditure. He reasoned that taxation falls on current incomes and primarily reduces current consumption and only secondarily saving. By contrast, borrowing falls entirely on savings, which for Ricardo and classical economists are identical to investment. As a consequence, public borrowing diminishes the investable product and has detrimental effects on the economy’s capacity to accumulate capital.

The empirical evidence from various countries does not lend support to the Ricardian equivalence in its pure form, although there is some evidence that saving rates follow government spending—that is, it has been observed that the personal saving rate increases in the case of deficit spending and decreases in the case of government surpluses. It is very hard, however, to show a direct one-to-one relationship here. A usual criticism of the Ricardian equivalence theorem is that real-life situations are characterized by uncertainty regarding future income and also tax liability, which prevents individuals from behaving in accordance to rational expectations. Furthermore, Ricardian equivalence does not hold in cases where the growth rate of the economy exceeds the rate of interest.

RICARDIAN VICE

The term *Ricardian vice*, which refers to the English economist David Ricardo (1772–1823), was coined by Joseph A. Schumpeter in his *History of Economic Analysis* (1954). It was intended to highlight Ricardo’s alleged habit of introducing utterly bold assumptions into an already oversimplified representation of the economy and treating these as given when in fact they are unknowns. In Schumpeter’s words, Ricardo’s “fundamental problem” was that he “wanted to solve in terms of an equation between four variables: net output equals rent plus profits plus wages” (Schumpeter 1954, p. 569). Operating with this perspective, Ricardo was bound to treat three of the variables as constants. Schumpeter also deplored Ricardo’s alleged habit of “piling a heavy load of practical conclusions upon a tenuous groundwork” (Schumpeter 1954, p. 1171). Two examples serve to illustrate what Schumpeter considered to be Ricardo’s inadmissible way of reasoning. The first is Ricardo’s famous suggestion, made in 1819, that the whole of the British national debt accumulated during the Napoleonic Wars could be repaid in a few years by means of a tax on property (Ricardo 1951–1973, vol. 5, pp. 38, 271). Such a tax, Ricardo argued, would not diminish total wealth and would also not unduly hurt the propertied classes, because the capital value of the current taxes levied on them to cover interest charges and amortization was equal to the lump-sum property tax suggested.
This proposal became known as Ricardo’s equivalence theorem. The second example is Ricardo’s view that the burden of a tax on wages or on goods consumed by workers will not be borne by workers (e.g., Ricardo 1951–1973, vol. 1, p. 203). Both conclusions are the logical consequence of the underlying premise that workers are paid a subsistence wage that cannot be changed. As Schumpeter opined, Ricardo’s theory of wages amounted to taking wages as fixed at the “subsistence” level (Schumpeter 1954, p. 665).

These criticisms elicit two remarks. The first concerns the way Ricardo reasoned. Apparently his critics have not taken seriously his statement that “in all these calculations I have been desirous only to elucidate the principle, and it is scarcely necessary to observe, that my whole basis is assumed at random, and merely for the purpose of exemplification. The results though different in degree, would have been the same in principle. … My object has been to simplify the subject” (Ricardo 1951–1973, vol. 1, pp. 121–122). Hence, while it is true that Ricardo frequently employed bold cases to “elucidate” the principle at hand and draw attention to what he considered the most important aspects of the problem under consideration, he certainly did not seek to prevent his readers from trying out less restrictive assumptions and investigating their implications, nor did he himself abstain from doing so. Some later commentators rightly praised him for having heralded an approach in economics that requires a clear statement of the assumptions on the basis of which certain propositions are taken to be valid within a given analytical context. This is now considered an indispensable prerequisite of scientific communication. Therefore what Schumpeter considered a vice, others took to be a virtue.

As regards the analytical core of Ricardo’s argument, it would be wrong to take Ricardo to have been a strict follower of the Malthusian concept of a subsistence wage. While he used this concept in some contexts for the sake of simplicity, in others he explicitly stressed the historical and social dimensions of the “natural wage” and warned that it must not be mistaken for a minimum required for physiological subsistence (see, e.g., Ricardo 1951–1973, vol. 1, pp. 96–97). He took into account the possibility that workers might receive a share of the social surplus product and maintained that the rate of profits is inversely related to “the proportion of the annual labour of the country devoted to the support of the labourers” (Ricardo 1951–1973, vol. 4, p. 49).

This brings us to the second observation, which concerns the fact that the “standpoint … of the old classical economists from Adam Smith to Ricardo has been submerged and forgotten since the advent of the ‘marginal method,’” as Piero Sraffa remarked perceptively (Sraffa 1960, p. v). By the turn of the nineteenth century it was no longer understood that the classical economists had advocated a theory of income distribution that was fundamentally different from the marginalist one. The marginalist approach sought to determine the rate of profits and the wage rate in terms of the respective factors of production, capital, and labor and thus on the basis of the economy’s given initial endowment of the factors. (With heterogeneous capital goods the amount of capital in given supply can be expressed only as a sum of value, which spoils the symmetry between the factors with [homogeneous] labor given in terms of its own natural unit.) The classical economists, on the contrary, determined the rate of profits for the system of production in use in terms of the “social surplus” left over after all used-up means of production and wage goods consumed by workers at a given wage rate have been deducted from gross output levels. Hence, whereas the marginalist authors treated profits and wages symmetrically, the classicals treated them asymmetrically. This asymmetric treatment was unimaginable to the marginalist authors, who therefore felt entitled to accuse the classical authors of treating as a constant what is a variable—that is, the wage rate. Schumpeter’s incomprehension was in fact anticipated by major marginalist authors, such as William Stanley Jevons and Léon Walras (see Kurz and Salvadori 2002, pp. 390–395). However, to treat wages as a given in one part of classical theory is a priori no less admissible than to treat the capital endowment as a given in one part of marginalist theory. As Sraffa (1960) has shown, the classical approach to the theory of value and distribution can be formulated in a coherent way that allows one to determine the unknowns (one of the distributive variables and relative prices) in terms of the givens, without depending on bold assumptions, such as the existence of a subsistence wage.

In light of these considerations and granting the fact that Ricardo based some of his arguments on highly simplified analytical constructions, it appears to be somewhat problematic to speak of “Ricardian vice.” One can only wonder whether it would be more appropriate to speak of “Schumpeterian incomprehension.”

RICARDO, DAVID
1772–1823

David Ricardo was born into a prolific Sephardic Jewish family in London on April 18, 1772. His father was a well-to-do stockbroker. David, already “when young, showed a taste for abstract and general reasoning” (Ricardo 1951–1973, Works, vol. 10, p. 4). At the age of fourteen he joined the business of his father. When at the age of twenty-one he married Priscilla Ann Wilkinson, a Quaker, his parents broke with him. Ricardo then began a highly successful career as a stockjobber. He made a fortune on the occasion of the Battle of Waterloo (June 18, 1815) by betting on a defeat of the Napoleonic troops.

CAREER AND WRITINGS

Ricardo’s interest in political economy was ignited by Adam Smith’s Wealth of Nations (1776), and it was amplified by economic events at the time, especially the Bank of England’s suspension of the convertibility of bank notes into gold in February 1797 and inflationary tendencies during the Napoleonic Wars. In 1809 Ricardo anonymously published his first article, “The Price of Gold,” in the Morning Chronicle. One year later he published the pamphlet The High Price of Bullion, a Proof of the Depreciation of Bank-Notes, which swiftly made him known in learned and political circles. The famous Bullion Report to the British House of Commons reflects his influence, and Ricardo became a major contributor in the Bullion controversy. (The controversy unraveled after the Bank of England in 1797 had suspended convertibility of its notes into gold. The Bullionists, including Ricardo, argued that the ensuing increase in money supply would lead to rising prices, whereas the Anti-Bullionists maintained that the money supply was driven by the “needs of trade” reflected by the real bills presented to the Bank for discount. The Bullion Report was strongly influenced by the monetary theorist Robert Thornton, a Bullionist.) In several letters to the Morning Chronicle and in a pamphlet titled Reply to Mr. Bosanquet’s “Practical Observations on the Report of the Bullion Committee” (1811), he defended the Bullion Report. In his hands, the quantity theory of money became a powerful weapon against the Bank of England’s inflationary expansion of money circulation, which, while beneficial to a few, was detrimental to the interests of the nation at large.

Eventually, Ricardo came to know James Mill (1773–1836) and Thomas Robert Malthus (1766–1834). Mill incessantly urged Ricardo to write down his ideas and publish them. With Malthus, Ricardo engaged in many controversial discussions until the end of his life. It was Malthus’s relentless criticism that forced Ricardo to rethink his positions and develop what he considered “a very consistent theory” (Works, vol. 7, p. 246).

Probably prompted by a move before Parliament to restrict the corn trade in early 1813, Ricardo started to investigate the impact of the accumulation of capital on the rate of profits. This resulted in March 1814 in some “papers on the profits of Capital,” which unfortunately have never been found, and in February 1815 in the publication of his Essay on the Influence of a Low Price of Corn on the Profits of Stock; Shewing the Inexpediency of Restrictions on Importation. The Essay was eventually to grow into his magnum opus, On the Principles of Political Economy and Taxation, published in April 1817. The book sold out in a few months. A second, substantially revised edition came out in 1819, and a third, carrying the new chapter “On Machinery,” in 1821. Ricardo’s “principal problem” in this work was to determine the “laws” that regulate the distribution of the product between the three classes of society—landowners, capitalists, and workers (Works, vol. 1, p. 5).

By late 1815 Ricardo had decided to withdraw from the Stock Exchange and invest his money in landed estates—a move supported by his theory of rent, according to which, in an “improving society,” ever larger parts of the soil of a country would become scarce and rise in price. In February 1816 Ricardo published some Proposals for an Economical and Secure Currency, in which he put forward anew his “ingot plan.” The plan suggested a return to the gold standard by making bank notes convertible into gold ingots rather than coins. This practice would allow Britain to continue to use paper as the actual means of payment and it would curb the huge profits of the Bank of England (a private institution until 1946), which in Ricardo’s view ought to accrue to the public rather than to the bank’s directors. In 1821, with the resumption of cash payments by the Bank of England, Ricardo’s plan was implemented.

In 1819 Ricardo became a member of Parliament by buying the seat of Portarlington, Ireland. He participated in many debates, mostly on monetary and financial matters. He became famous for his suggestion in 1819 to
Ricardo, David

repay the whole of the national debt in a few years by means of a tax on property. Ricardo argued that such a tax would not diminish total wealth and would also not unduly hit the propertied classes because the capital value of the current taxes levied on them to cover interest charges and amortization of the national debt was equal to the lump-sum property tax suggested. This proposal became known as “Ricardo's equivalence theorem.”

After the publication of the first edition of the Principles, Ricardo was predominantly concerned with the problems of value and distribution, the measure of value, and the machinery question. The second edition brought substantial changes in the chapter “On Value.” In the third edition, he withdrew his earlier optimistic view on the swift compensation of labor displacement due to the introduction of improved machinery.

Ricardo died at his country seat, Gatcombe Park in Gloucestershire, on September 11, 1823, from an “infection of the ear, which ultimately extended itself to the internal part of the head” (Works, vol. 10, p. 12).

Ricardo on Value, Distribution, and Capital Accumulation

In this entry, emphasis will be placed on Ricardo's contributions to the theory of value, distribution, and capital accumulation. For his views on money, taxation, public debt, and politics, see Giancarlo de Vivo (1987), Samuel Hollander (1979), and Murray Milgate and Shannon Stimson (1991).

Ricardo, a man with considerable practical sense and experience, always defended economic theory against the “vulgar charge” of those who are “all for fact and nothing for theory. Such men can hardly ever sift their facts. They are credulous, and necessarily so, because they have no standard of reference” (Works, vol. 3, pp. 160, 181).

Ricardo adopted Smith's long-period method, which focuses attention on “natural” as opposed to “market” prices and thus on the persistent and systematic as opposed to the temporary and accidental factors at work in the economic system. However, Ricardo gave greater emphasis to the members of the “monied class” in bringing about, in conditions of free competition, a tendency toward a uniform rate of profits (see Works, vol. 1, p. 88).

Ricardo offered clear statements of the principles of extensive and intensive diminishing returns in agriculture due to the scarcity of land. While Ricardo was not the first to discover these principles, he deserves credit for their incorporation into a system of political economy whose main aim was the determination of the general rate of profits. With extensive diminishing returns, different plots of land can be brought into a ranking of natural “fertility” that corresponds to the ranking of unit costs of the agricultural product, say corn. With very low levels of production of corn, only land of the highest fertility will be cultivated and there will be no rent, for essentially the same reason that nothing is given for “the gifts of nature which exist in boundless quantity” (Works, vol. 1, p. 69). It is only as capital accumulates and population grows that land of second and third quality, and so forth, will have to be cultivated in order to satisfy a growing social demand. As a consequence, the price of corn will have to rise relative to that of other commodities. The price is determined on no-rent-bearing (i.e., marginal) land and equals unit costs (including profits at the normal rate) on it; the owners of intramarginal lands obtain differential rents reflecting lower unit costs. From this Ricardo concluded against Smith that rent “cannot enter in the least degree as a component part of its price” (see Works, vol. 1, p. 77). In addition, rent was not an expression of the generosity of nature, but of its “niggardliness”; it was not the cause of the high price of corn, but its effect.

Setting aside “improvements” in agriculture and assuming a given and constant real wage rate, an extension of cultivation while increasing the surplus product involves an ever larger part of it being appropriated as rent. It follows that the “natural tendency of [the rate of] profits then is to fall” (Works, vol. 1, p. 120). The fall is not due to an intensified “competition of capitals,” as Smith had maintained, but to diminishing returns in agriculture (and mining).

Profits in turn depend on wages. As is the case with all commodities, Ricardo distinguished with regard to labor between its “natural” and its “market” price. The former is defined in conjunction with the rate of capital accumulation: in an “improving society,” natural wages are typically higher than in a stagnant one because, via the wage rate, the growth of population is attuned to the requirements of accumulation. Ricardo also stressed the historical and social dimensions of the natural wage and warned that it must not be mistaken for a purely physiological minimum of subsistence (Works, vol. 1, pp. 96–97). He even contemplated the possibility that the “population may be so little stimulated by ample wages as to increase at the slowest rate—or it may even go in a retrograde direction” (Works, vol. 8, p. 169). Therefore, Ricardo can hardly be called a strict adherent to Malthus's “law of population.” He also discussed the possibility of workers participating in the sharing out of the surplus product. In this case, he felt the need to replace the concept of a given real (i.e., commodity) wage rate by a share concept, or “proportional wages” (Sraffa 1951, p. lii), that is, “the proportion of the annual labour of the country … devoted to the support of the labourers” (Works, vol. 1, p. 49). It was on the basis of the new wage concept (and on the premise that the social capital consisted only of, or could be reduced to, wages) that Ricardo then asserted
what was called his “fundamental proposition on distribution”: that the rate of profits depends on proportional wages, and on nothing else.

One element of Ricardo’s theory of profits has particularly puzzled his interpreters. In a letter written in March 1814 he stated: “It is the profits of the farmer which regulate the profits of all other trades, and as the profits of the farmer must necessarily decrease with every augmentation of Capital employed on the land, provided no improvements be at the same time made in husbandry, all other profits must diminish and therefore the rate of interest must fall” (Works, vol. 6, p. 104). According to the Italian economist Piero Sraffa (1898–1983), the “rational foundation” of the “basic principle” of the determining role of the profits of agriculture was that “in agriculture the same commodity, namely corn, forms both the capital (conceived as composed of the subsistence necessary for workers and the product), so that “the determination of the ratio of this profit to the capital, is done directly between quantities of corn without any question of valuation” (Sraffa 1951, p. xxxi). In order for other trades to earn the same competitive rate of profits, their prices have to adjust relative to corn. Sraffa was careful to stress that this model was “never stated by Ricardo in any of his extant letters and papers.” Yet although direct evidence is missing, Sraffa saw enough indirect evidence to support this view (Sraffa 1951, p. xxxi). It is interesting to note that the “basic principle” that Sraffa ascribes to Ricardo was clearly spelled out by Robert Torrens (1780–1864), who called it a “general principle” and acknowledged his indebtedness to Ricardo (1820, p. 361).

Malthus’s insistence that capital never really consists of a single commodity that is identical with the product obviously required a deeper analysis. This forced Ricardo in the Principles to abandon his corn-ratio theory in favor of the labor-embodiment principle of value. Whereas in his early theory the rate of profits was conceived as the ratio between two quantities of corn, it was now conceived as the ratio between two quantities of labor: the amount of labor “embodied” in the surplus product (exclusive of the rents of land) and the amount embodied in the social capital (where Ricardo frequently identified capital with wages). This change was possible by introducing the hypothesis that commodities exchange according to the direct and indirect labor necessary in their production. In this way, bundles of heterogeneous commodities are made commensurable. The new theory replicated the important finding that the rate of “profits would be high or low in proportion as wages were low or high” (Works, vol. 1, p. 111). The labor theory of value enabled Ricardo to dispel the idea deriving from Adam Smith’s “adding-up theory” of prices (Sraffa 1951) that wages and the rate of profits could move independently of one another and to establish the constraint binding changes in the two distributive variables, given the system of production. It was an ingenious move that allowed him, or so he thought, to free the simple inverse relationship between wages and the rate of profits from “a labyrinth of difficulties” (Works, vol. 6, p. 214) caused by price movements.

However, Ricardo was aware of the fact that his “general rule” of value was “not rigidly true” (Works, vol. 7, p. 279) and was “considerably modified by the employment of machinery and other fixed and durable capital” (vol. 7, p. 30). Different proportions of means of production and direct labor, along with different durabilities of capital goods employed in their production, would make the relative prices of commodities depend on income distribution: the higher the rate of profits (and, correspondingly, the lower the wages), the relatively more expensive will be commodities produced with a high proportion of means of production to labor and means of production that are long-lived. The fact that “profits [are] increasing at a compound rate … makes a great part of the difficulty” (Works, vol. 9, p. 387).

This fact threatened to undermine Ricardo’s novel solution to the theory of profits. The task of finding a way out of the impasse occupied him until the end of his life. Apparently, to play down the modifications to the labor theory of value as unimportant was not good enough (see Works, vol. 9, p. 178). He sought to cope with this problem in terms of his concept of an “invariable measure of value” (see Kurz and Salvadori 1993). Originally, that concept was designed by Ricardo for the purpose of carrying out interspatial and intertemporal comparisons, that is, comparisons relating to different technical environments. An invariable standard of value would consist of a commodity produced with an unvarying quantity of total labor. Hence, if another commodity varied in value relative to the standard, it would be clear that this was due to a change in the quantity of labor bestowed on the production of that commodity.

Ricardo now had to face the entirely different problem that even in a given technical environment two commodities may vary in relative value consequent upon a change in income distribution. This was due to the “variety of circumstances” under which commodities are produced (Works, vol. 4, p. 368). Ricardo tried to tackle the problem in terms of searching for a standard of value that would have to be a “medium between the extremes” (vol. 4, p. 372). While Ricardo’s discussion of this problem is layered with different meanings, and is not always very clear, there can be no doubt that the main purpose of his investigation was to elaborate a consistent theory of value and distribution. This necessitated first and foremost unraveling the properties of a given system of social production as regards the set of alternative constellations of distribution and relative prices compatible with it.
However, since he did not fully master the subject, Ricardo, for lack of a more satisfactory theory, clung to a doctrine that, he felt, offered a sufficiently solid ground to stand on: the labor theory of value. Embodied labor was seen by him to be the main determinant of value and somehow, he thought, both “invariability” requirements could be formulated in terms of a standard that fared well on both counts. The standard had to be produced by a constant amount of labor and by medium circumstances. As regards the second requirement, by expressing bundles of commodities such as the surplus product distributed as profits on the one hand and social capital on the other in terms of such a standard, the positive and negative deviations of prices from labor values could, in each aggregate, be expected to balance. This would allow one to continue to envisage the rate of profits as a ratio of two quantities of labor and thus depend on “the proportion of the annual labour of the country devoted to the support of the labourers” (Works, vol. 4, p. 49). The measure was designed to corroborate Ricardo’s dictum that the laws of distribution “are not essentially connected with the doctrine of value” (Works, vol. 8, p. 194).

While there is no general theoretical solution to Ricardo’s first problem, Sraffa (1960), in terms of the concept of “standard commodity,” provided a solution to a somewhat reformulated version of Ricardo’s second problem. It goes without saying that Ricardo was wrong in assuming that two birds can be killed with one stone (see Kurz and Salvadori 1993).

The theory of value and distribution formed the analytical centerpiece of Ricardo’s political economy. It was designed to lay the foundation of all other economic analysis, including the investigation of capital accumulation and technical progress, of development and growth, of trade, and of taxation and public debt.

Like Adam Smith, Ricardo advocated free trade, but he felt that an explanation of the pattern of trade in terms of absolute cost advantages was unsatisfactory. He elaborated the principle of comparative cost and illustrated it in terms of a famous numerical example involving two countries, Portugal and England, and two commodities, cloth and wine. He showed that even if Portugal were to have an absolute advantage in the production of both commodities, there would be room for mutually beneficial trade provided Portugal specialized in the production (and export) of that commodity where its absolute advantage was relatively larger, wine, while England specialized in the production (and export) of the commodity where its absolute disadvantage was relatively smaller, cloth. The effect of foreign trade could be an augmentation of the riches of both trading countries. Ricardo’s principle of comparative cost was called the “deepest and most beautiful result in all of economics” (Findlay 1987, p. 514).

In the Principles, a great deal of attention is devoted to taxes, the problem of tax incidence, and the impact of taxes on capital accumulation. Ricardo stressed that “there are no taxes which have not a tendency to lessen the power to accumulate. All taxes must either fall on capital or revenue.” However, he added: “Taxes are not necessarily taxes on capital, because they are laid on capital; nor on income, because they are laid on income.” (Works, vol. 1, p. 152). The problem of tax incidence is then illustrated in a number of cases. For example, on the premise that workers are paid a subsistence wage, a tax on wages could not be borne by workers: nominal wages would have to rise, leaving real wages constant, and the tax would accordingly be borne by capitalists. (This premise also underlies Ricardo’s tax proposal to repay the national debt.) The situation is similar when a tax is laid on a wage good. In accordance with his doctrine that rent does not enter price, Ricardo concluded that “a tax on rent would affect rent only; it would fall wholly on landlords, and could not be shifted to any class of consumers” (vol. 1, p. 171). A tax on profits would raise the prices of products: “if a tax in proportion to profits were laid on all trades, every commodity would be raised in price” (vol. 1, p. 205). Depending on the consumption patterns of the different classes of society, this would affect their members differently. A rise in the price of wage goods would again entail a corresponding adjustment of nominal wages: “whatever raises the wages of labour, lowers the profits of stock; therefore every tax on any commodity consumed by the labourer, has a tendency to lower the rate of profits” (vol. 1, p. 203).

Ricardo’s treatment of taxes, while containing many interesting ideas and suggestions, is generally not considered to be the strongest part of his book and is said to suffer from a poor arrangement of the material and an argument that is frequently tied to excessively restrictive assumptions, such as constant real wages.

**BIBLIOGRAPHY**

**Right Wing**

The term *right wing* originated with the seating arrangement of the French National Assembly of 1791. The royalists sat on the right side of the chamber while their opponents were seated to their left on an elevated section called the Mountain. Between them sat a mass of deputies, known as the Plain, who did not belong to any particular faction.

### Opposition to the French Revolution

The Right, representing aristocratic, royalist and clerical interests, supported the monarchy. The Left called for a limited monarchy and a unicameral legislature. But these labels took on new meanings during the course of the French Revolution. Although originally advocates for moderate reform, the powerful Jacobin clubs became increasingly radicalized as popular figures such as Maximilien Robespierre, Louis St. Just, and Jean-Paul Marat, whose inflammatory rhetoric led to the execution of King Louis XVI and the Reign of Terror, gained influence. Eventually, anyone who defended the monarchy was regarded as a member of the Right.

Since the beginning of the French Revolution, right-wingers typically have resisted calls for revolutionary change. The earliest and perhaps the most famous and influential of them, English statesman Edmund Burke (1729–1797), furiously denounced the *armed doctrines of the revolutionaries* in his *Reflections on the Revolution in France* (1790). He appealed to custom, tradition, religion, prescriptive rights, and social hierarchy. Many subsequent critics of the Revolution acknowledged their intellectual debt to Burke. They believed that the Revolution threatened not only traditional institutions and arrangements but the very foundations of European civilization itself.

### Changing Meanings

What it meant to be a right winger would vary depending on the country, culture, and the particular issue. English conservatives, for example, opposed the Utilitarians, or Classical Liberals, who favored free market economics and minimal government. But by the end of the nineteenth century, the positions were reversed. As the Left embraced socialism, the Right became defenders of the free market.

For nearly two centuries, these competing groups battled each other mostly over questions of economics and class. The Right defended the property rights of the privileged classes while the Left sought to equalize wealth and property. For the most part, they debated the extent to which wealth should be redistributed through government intervention. In the early-twenty-first century, cultural and social issues, such as abortion, same-sex marriage, secularism, and multiculturalism, have come to play a more dominant role in Left-Right political struggles.

### The Right Wing in the Twenty-First Century

Although there is little consensus over what is meant by right wing, most persons of the Right would subscribe to a basic set of beliefs. The Right gives greater primacy to liberty than equality. Social hierarchy is not only the natural order of things, but desirable. Human nature is fixed and cannot be perfected. Original sin or inherent defects of character explain our proclivity toward violence and evil. Members of the Right generally value religion (usually Christian) as a civilizing force. Culture matters more than either politics or economics. With the exception of the authoritarian Right and radical libertarians, right-wingers detest both collectivist and extreme individualist ideologies. Believing that humans are social creatures, right-wingers hold that people find meaning and purpose in their existence through membership in strong, viable groups such as family, voluntary associations, church, and local community. They equally condemn all efforts to either collectivize or atomize society. Because of the importance right-wingers place on cultural, ethnic, and national particularity, they oppose globalist and multicultu-
tural ideologies as inimical to rooted communities. Aware of the limited capacity of human beings for reason, right-wingers believe that traditions and prescriptive institutions are more reliable guides to general happiness and harmony than most proposals for change. They would agree with Samuel Johnson’s famous observation that “most schemes of political improvement are very laughable things” (Boswell 1980).

The Right can be divided into three basic categories: reactionary, moderate, and radical or extreme. The reactionary Right longs nostalgically for the ancien régime. They are aristocratic, authoritarian, and often pre-Reformation Catholics. Such views are rarely heard in the early-twenty-first century.

Most members of the moderate, democratic Right can trace their intellectual lineage to Burke, the father of modern conservatism. They reject the Jacobin philosophy of universal rights and the extreme individualism of the Utilitarians, and stress the importance of family, tradition, and religion as indispensable mainstays of civilized existence. Moderates favor limited constitutional government. In U.S. politics, the democratic Right can be broken down further into paleoconservative, neoconservative, and libertarian camps. The paleoconservatives are a group of traditionalists or Old Rightists who support minimal government, traditional institutions, and an isolationist foreign policy. They oppose liberal immigration policies. The neoconservatives are mostly Jewish intellectuals who moved to the Right in response to the excesses of the Left during the 1970s. They propose big-government conservatism with a welfare-state component, foreign policy crusades to spread democracy and human rights, and liberal immigration policies. Although defined as right-wingers by the popular media, the libertarians do not share many of the philosophical principles of the Right. They place a greater faith in human rationality and tend to be extreme individualists. Most problems, they believe, can be resolved through the free workings of an unregulated marketplace. Minimal taxes, small government, and laissez-faire economics are the hallmark positions of the libertarians.

Included as well under the rubric of right-wing is the Religious Right, a collection of Christian groups that share a common concern with the decline of moral values in U.S. society and crusade against abortion, same-sex marriage, and the secularization of public school instruction. Also affiliated with the Right are a variety of single-issue groups such as anti-gun-control advocates and tax protesters.

The radical Right groups share few opinions other than extreme nationalism, nativism, and a tendency to spin conspiratorial theories. The John Birch Society, the Ku Klux Klan, neo-fascists, and militia groups are a few representative examples. Most oppose immigration and are racialists such as Jean-Marie Le Pen’s Front National movement in France. Others, such as the Ku Klux Klan, White Peoples Party, and neo-Nazis, are overtly racist.

Like those on the Left, who prefer to be called progressive, people on the Right generally do not apply the label right-winger to themselves. More frequently, the Left labels its opponents as right-wingers to distinguish themselves and to define those on the Right as outside of the political mainstream.

RIKER, WILLIAM
1920–1993
William Harrison Riker pioneered the use of mathematical reasoning in the study of politics, an approach he termed “positive political theory.” The method was positive because of the aspiration to explain observed behavior rather than to make normative prescriptions for how people should behave. It was “theoretical” in the same sense as neoclassical microeconomics in that it used axiomatic methods, especially game theory, to derive a coherent set of propositions that comport with observed behavior.

Riker’s early work focused on the development of theories of legislative behavior. Of particular import was The Theory of Political Coalitions (1962), which used mathematical methods to identify the optimal size of a voting coalition. Previous work suggested that legislators or candidates in election campaigns should work to maximize the number of votes for preferred measures (Downs 1957). Riker’s argument was that this behavior would not be rational in settings, such as the distribution of pork-barrel spending, where resources allocated to the benefit of one actor do not benefit others. Instead, he argued that legislators would prefer to belong to a minimum winning coalition that restricted the number of individuals with a claim to the benefits of a particular program.

Another influential work by Riker, written with the political scientist Peter Ordeshook, was “A Theory of the Calculus of Voting” (1968), which elaborated a rational choice model of voter turnout. They argued that rational citizens should not participate if their goal is to influence election outcomes because the probability that their vote would be decisive is essentially zero. Instead, they argue that the factor motivating participation is the sense of satisfaction people get from performing their civic duty. Critics suggest that Riker and Ordeshook’s model of political participation is evidence of the nonfalsifiability of microeconomic models because the effect of civic duty has the flavor of a post hoc rationalization for why rational citizens participate when they get no benefit in expectation from the activity (Green and Shapiro 1994).

Riker’s later work turned to fundamental questions about the effects of political institutions. In Liberalism against Populism (1982), Riker builds on the intuition from Arrow’s Theorem that democracies are no better than other political systems at achieving socially desirable (pareto optimal) outcomes. He argues that the real value of democratic political systems is not their ability to make good decisions, especially given the possibility of social choice problems, but is instead the public’s ability to punish leaders. In The Art of Political Manipulation (1986), Riker considers how politicians can strategically manipulate the issues they bring to the fore for political advantage.

Riker’s contributions as an institution builder may be even more influential and long lasting than his scholarship. At the University of Rochester in New York, he was given wide latitude to construct a political science department whose faculty and students shared his interest in developing a positive political theory. His success in this endeavor is highlighted by the fact that the Rochester School came to be associated with the body of knowledge derived from the methodological and theoretical orientation Riker advanced, with adherents at almost every major American university. Not wanting to limit the advancement of social science to the study of politics, Riker was instrumental in the formation of the Public Choice Society, which helped positive political theorists form connections with sister disciplines in economics, sociology, public finance, and even philosophy.

RIOT ACT, THE
SEE Riots.

RIOTS
A riot is a social occasion involving relatively spontaneous collective violence directed at property, persons, or
authority. Five main concepts characterize a riot. First, riots are socially constructed in that those participating in them define or redefine their social environment through a negotiation or renegotiation of symbols and meanings. For example, if looting occurs during a riot, what is conventionally defined as stealing private property may come to be redefined as “taking” or “receiving” items that are now collectively considered within the domain of public property. Second, riots are not singular events or moments in time, but occasions, in that there is a “before,” “during,” and “after.” Although a riot may have an immediate precipitating incident, this moment is only one among many in the processional history of a riot. For example, the Watts Riot (August 1965) began with a relatively routine traffic stop of an African American motorist and quickly escalated into six days of arson, rock throwing, looting, and sniping that resulted in thirty-four dead and $45 million in damages. Though the traffic stop was the precipitating incident, it would not be correct to consider it the cause of the riot; rather, the cause was the cumulative effect of many events and circumstances. Third, a riot is relatively spontaneous in that it does not involve a significant amount of planning and coordination. Although a small number of individuals may instigate a riot and serve as emergent leaders by providing examples of “appropriate” behavior, these individuals are generally unable to plan and coordinate action in a meaningful way once a riot has begun. The relative spontaneity of riots led some of the earliest researchers to conclude that once in crowds, individuals became irrational, highly suggestible, and without social control. More recent research, however, has found these claims to be largely unsubstantiated, noting that during most riots, collective violence is purposive and targeted. Fourth, a riot involves collective violence, meaning that groups or communities engage in the infliction of harm or destruction for the purpose of producing social change. Although individual violence may produce social change and even rioting—as in the case of the assassination of Martin Luther King (April 4, 1968)—to be considered a riot, both collective action and violence for the purpose of social change must be present. Finally, a riot involves collective violence directed at property, persons, or authority. It is important to note that in many instances, collective violence is directed not solely at property, persons, or authority but at some combination, such as state-controlled property or persons in authority. For example, in reaction to Italian Reform Minister Roberto Calderoli wearing a shirt decorated with cartoons satirizing the Muslim prophet Muhammad, hundreds of Libyans rioted by throwing stones and burning the Italian embassy, killing ten (on February 17, 2006).

TYPES OF RIOTS

Just as actors participate in a variety of actions during a riot, so too are there different types of riot. There are four main categories of riot, though these distinctions are not mutually exclusive. A communal riot is characterized by collective violence directed at persons of an opposing group, and may involve racial, ethnic, or religious groupings. Although police or agents of social control may engage in violence to keep the groups apart, the vast majority of collective violence occurs between groups. A commodity riot is characterized by collective violence directed primarily at property, but may involve people of different groups. Next, a protest riot involves spontaneous collective violence directed against a specific policy. In contrast to the communal riot, during a protest riot most of the collective violence occurs between the police or other agents of social control and the rioters. The final, and perhaps most frequent, form of rioting is the revelry or celebration riot. As with a commodity riot, collective violence is directed primarily at property, but may involve persons. However, in contrast to all other riots, a celebration riot does not necessitate grievance and often occurs after a victory over a traditional rival or the winning of a championship.

A riot is distinct from a variety of concepts that are often employed interchangeably in popular usage. The term most frequently used as an equivalent is demonstration. However, a demonstration is distinct from a riot in three fundamental ways. First, a demonstration is often planned and thus lacks the relative spontaneity of a riot. Second, unlike a riot, collective violence does not need to occur for something to be considered a demonstration. Finally, during a demonstration, leaders often have enough control to coordinate and direct the actions of others, which rarely, if ever, happens during a riot. Another term often used interchangeably with riot is protest, which is the act of expressing grievance in hopes of achieving amelioration or to draw attention to a cause. A key feature of protest is the condition of grievance, which although sometimes present is not always necessary for a riot.

A riot is also distinct from a revolt, which is an action aimed at the overthrow of an established social order, which may involve a transfer of power and the radical restructuring of social relations. Although riots have the potential to produce some social change, they are perhaps better understood as “proto-political” movements that rarely, if ever, result in a transfer of power from one social group to another.

HISTORY OF THE RIOT

The current understanding of the term riot dates back to the fourteenth century, when it began to connote vio-
ience, strife, or disorder on behalf of a particular portion of the populace. By the early eighteenth century, violence and strife was on the rise in England, which resulted in Parliament passing the Riot Act of 1715. The Riot Act stated that if twelve or more persons unlawfully or riotously assembled and refused to disperse within an hour after being read a specified portion of the act by proper authority, those persons would be considered felons and authorities would have the right to use lethal force against them. The Act provided broad powers to institutional authority during riots and despite some notable riots over the next two centuries, resulted in a general decline in the number and severity of riots in England. Although repealed in 1973, the Riot Act was influential in providing a legal framework for similar legislation in many other nations, including Australia, Belize, Canada, and the United States. From 1965 to 1973 the United States experienced a significant increase in the number of domestic riots, particularly in large urban areas with high concentrations of poverty and racially based residential segregation. Some community members from these areas objected to the term riot, as they believed it called to mind the image of an unruly ghetto. Consequently, many scholars and politicians began to refer to riots as civil disorders. Although riot no longer appears to have this same negative connotation and again appears in popular and social science terminology, the term civil disorder is still often used interchangeably.

Recent research by social scientists has again sparked interest in the study of riots. In a comprehensive review and reanalysis of riots in the United States during the 1960s and 1970s, Clark McPhail (1994) found that a lack of resources, grievance, and aggression did not play as large a role in riots as originally claimed. In addition, McPhail found that actors in a riot are far more purposive in their actions than previously supposed. However, McPhail’s findings regarding the causes of riots may be limited in generalizability, as research by Ashutosh Varshney (2002) found urban, caste, and community factors to be predictors of riots in India. This renewed interest in riots highlights the need for a better understanding of where and why they are likely to occur.

RISK

The concept of risk is fundamental in the social sciences. Risk appears in numerous guises, from theoretical modeling of financial decisions to determining the social consequences of expanded nuclear power usage. Despite this importance, the precise definition of risk depends on the context and application. Common usage is derived from insurance applications where risk represents the possibility of loss, injury, or peril. This definition is reflected in various risk assessment and management applications, ranging from social and psychological risk to environmental and biohazard risk, where units of measurement for risk vary with context. In contrast, financial economics associates risk with the possibility that the actual return for a security will differ from the expected return. This financial risk is typically measured using the variance or standard deviation of historical return from the mean return, a definition of risk that includes both positive and negative outcomes. Key theoretical notions such as risk aversion and the risk-return tradeoff employ this definition. Where only the possibility of financial loss is of concern, as in value-at-risk applications, measurements are evaluated using the left tail of the relevant probability distribution.
RISK, UNCERTAINTY, AND PERCEPTION

The evolution of methods for the identification, assessment, and management of risk have played a central role in the progress of civilization. In ancient times, religious beliefs were important in reconciling the risks confronting a society. Appeals to the gods by the priesthood, prophecies from the oracle, and chanting by the shaman were all methods of passively dealing with risks encountered. The development of scientific, mathematical, and probabilistic methods during the Enlightenment permitted risk to be more actively identified and assessed. This advancement encountered a philosophical quandary concerning subjective and objective interpretations of probability. More precisely, the objective interpretation views probability as inherent in nature. Logic, scientific investigation, and statistical analysis can be used to discover objective probabilities. In contrast, subjective probabilities quantify an individual's belief in the truth of a proposition or the occurrence of an event and are revealed in an individual's choice behavior. Such probabilities can vary among individuals due, for instance, to differing degrees of ignorance about the event of interest.

Debate over subjective versus objective probability reached a peak around the time that Frank Knight (1885–1972) introduced a distinction between risk—where the objective probability of an event is at least measurable—and uncertainty, where the probability is not knowable and has to be determined subjectively. This terminological distinction between risk and uncertainty has now faded from common usage as the subjectivist approach has gained prominence, supported by seminal contributions from Frank Ramsey (1903–1930), Bruno di Finetti (1906–1985), and Leonard Savage (1917–1971). Attention has shifted to whether subjective beliefs derive from intuition or are realized only in choice behavior. The intuitive approach leads to a focus on the perception of risk, a concept often employed in psychometric and sociological research. Development of the choice-theoretic approach to subjective probability was facilitated by the expected utility function introduced by John von Neumann (1903–1957) and Oskar Morgenstern (1902–1976) in a classic work of social science, *The Theory of Games and Economic Behavior* (1944). The choice-theoretic approach has sustained the modeling of decision-making under uncertainty that is a central component of modern economic theory.

RISK IN ECONOMICS

Prior to von Neumann and Morgenstern, mathematically formal neoclassical economic theory was based on certainty or perfect foresight. Consideration of risk in decision-making could be found in the less formal approaches of Frank Knight, John Maynard Keynes (1883–1946), and Irving Fisher (1867–1947) that have contributed to a range of future contributions and perspectives on the impacts of risk in economics. Knight’s recognition that uncertainty could be handled by the insurance principle led to contributions on the importance of moral hazard and adverse selection in decision-making under uncertainty. By explicitly recognizing what he termed the “caution coefficient,” which measures the difference between the mathematical expectation and the price that will be paid for a gamble, Fisher laid the foundation for later contributions in mean-variance portfolio theory. The numerous contributions by Keynes on risk and uncertainty range from the *Treatise on Probability* (1921) to the *General Theory of Employment, Interest and Money* (1936). Disciples of Keynes, such as George L. S. Shackle (1903–1992) argue against the use of probability theory to model decision-making under uncertainty. Similarly, the failings of the ergodicity assumption are an important post-Keynesian critique of mathematically formal economic theory.

In addition to the diverse approaches to risk generated by Knight, Keynes, and Fisher, the application of mathematical formalism in economic theory has also produced impressive progress. Using preference orderings over state contingent commodities, Kenneth Arrow (born 1921) and Gerard Debreu (1921–2004) were able to extend the neoclassical economics of Stanley Jevons (1835–1882), Léon Walras (1843–1910) and Alfred Marshall (1842–1924) to include decision-making under uncertainty. This development follows naturally from using the choice-theoretic approach to subjective probability developed by von Neumann and Morgenstern. The utility of a certain outcome is replaced by the expected utility, calculated using known probabilities and the utilities for a set of random outcomes. The known probabilities are notionally determined by direct observation of previous choice behavior. Using this approach, while there is no formal distinction between risk and uncertainty, risk is usually associated with the variability of random outcomes and uncertainty with randomness. Sensitivity to risk is measured by comparing a certain outcome to a random outcome with the same expected value. Risky outcomes are measured in income, dollars, or returns, and can take both positive and negative values.

In financial economics, the expected utility framework has been applied to the problem of determining how to optimally combine individual securities into a portfolio of securities. Using an expected utility function specified over the expected portfolio return and variance of portfolio return, Harry Markowitz (born 1927) and William Sharpe (born 1934) were able to demonstrate that the variability or risk of a portfolio can be further divided into two components: firm-specific risk, which is diversifiable.
and non-systematic; and market related risk, which is systematic and not diversifiable. Applying this to the tradeoff between risk and return, it is demonstrated that only increases in the systematic risk of an individual security will be rewarded with higher expected return. Hence, it is only that portion of the total variability of a security’s return that cannot be diversified away that warrants higher expected return. A measure of systematic risk—the beta of a security—is provided. Beta can be calculated as the slope coefficient in a least squares regression of individual security return on market return: the ratio of the covariance between the individual security return and the market return divided by the variance of the market return. More recently, a variety of risk measures have been developed to deal with limitations of variance of return and beta. These new measures include expected regret, conditional value at risk, and expected shortfall.

**RISK IN OTHER SOCIAL SCIENCES**

In social sciences other than economics, risk is usually identified with only negative outcomes. Units of measurement vary and can include the annual death toll, deaths or injuries per hour of exposure, loss of life expectancy, loss of working hours, accidents per mile driven, and crop loss per storm. A wide range of risk definitions and risk models are employed, including the classical approach based on objective probabilities, adapted from engineering and medicine; the choice-theoretic expected utility approach employed in economics; and the risk perception approach popular in sociology and psychometrics, where it is explicitly recognized that risk depends on cultural and individual perceptions that can differ from expert or objectively specified risk estimates. Because a variety of different negative outcomes can be of interest, measures of risk vary with the consequences involved. For example, in the classical approach, risk is defined as the loss or hazard if the event occurs times the probability the event will occur. In other words, risk is a combination of exposure and uncertainty. However, when risk involves an event such as death, then risk relates only to the probability of the event occurring.

In many situations in the social sciences, the application of objective probabilities to determine risk is problematic. Though it is possible to specify the relative frequency of a negative outcome from past data, the data is often limited and the estimated risk can be less than objective. In addition, because risk depends on the context, there is room for disagreement over the selection and measurement of relevant consequences. This poses problems in studies of perceived risk where individual perceptions are compared with calculated risk obtained from expert or objective estimates. Early studies on risk perception were concerned with determining whether there were significant deviations between individual risk perceptions and expert estimates. If such deviations were present, this provided support for the presence of heuristics and other sources of probability judgment bias. Further research has revealed that risk perception is a more complicated phenomenon. For example, risk perception depends on the target selected. This is manifested in risk denial, where individuals perceive risk to the general public from, say, alcohol or nuclear waste, to be greater than perceived risk to the individual or the individual’s family.

**RISK NEUTRALITY**

*Risk neutrality* is an economic term that describes individuals’ indifference between various levels of risk. When confronted with a choice among different investment opportunities, risk-neutral decision makers only take into account the expected value of the alternative and not the associated level of risk. For example, a risk-neutral investor will be indifferent between receiving $100 for sure, or playing a lottery that gives her a 50 percent chance
of winning $200 and a 50 percent chance of getting nothing. Both alternatives have the same expected value; the lottery, however, is riskier.

In economic theory it is generally accepted that most individuals are not risk-neutral. People tend to prefer safer choices to riskier ones, meaning they are risk-averse. In the above example, a risk-averse person would prefer getting the expected value of the lottery for sure rather than choose the gamble. In other words, a risk-averse person would require a premium above the expected value in order to play this lottery. Risk-neutral individuals would neither pay nor require a payment for the risk incurred.

In terms of utility theory, a risk-neutral individual's utility of expected wealth from a lottery is always equal to his or her expected utility of wealth provided by the same lottery. This implies a linear utility function, or relationship between the wealth and the utility of wealth. A simple example of such utility function is \( U(W) = W \), where \( W \) is wealth and \( U(W) \) is utility of wealth. In this case, a one-dollar increase in wealth will always result in the same increase in utility for any starting wealth level.

In finance, modern portfolio theory states that an investor needs to be compensated for the risk that she takes by receiving extra expected return. Such compensation is referred to as risk premium. The fact that historical returns for riskier asset classes, such as equities, consistently outperform returns for less risky assets (such as Treasury bills) confirms the existence of a considerable risk premium. For example, John Campbell, Andrew Lo, and A. Craig MacKinley reported in 1997 that in the period from 1889 to 1994 U.S. stock market returns were on average 4.18 percent higher than the returns on commercial paper. Risk neutrality, on the contrary, implies that investors do not require any risk premium since they are indifferent to the level of risk (p. 308). Therefore, in a world consisting of risk-neutral investors the difference between stock and commercial paper returns would be expected to be zero.

While risk neutrality is uncommon in the real world, the concept of risk neutrality plays an important role in option pricing. Risk-neutral valuation of options was first introduced by John Cox and Stephen Ross in 1976, and further developed by Cox, Ross, and Mark Rubinstein in 1979. This method is based on an observation that prices of derivatives are the same in the real as in the risk-neutral world. The risk preferences of individuals and the shape of their utility function do not affect the option prices as long as the agents prefer more wealth to less (the so-called nonsatiation condition). The fact that option prices are not affected by different preferences and utility functions of individuals allows us to price the options by calculating their expected values in the risk-neutral world and to use the risk-free discount rate to find their present value. The risk-neutral valuation principle is widely used in practice to calculate values of different financial derivatives.

**RISK TAKERS**

To take risks is to make decisions for which the favorability of outcomes is uncertain. Therefore, every individual and business entity is a *risk taker* at some level. However, the existence of risk takers who are prepared to put their capital and/or reputation at risk in the hope of a financial reward is a necessary precondition for a capitalist model of society. In the discipline of financial economics, risk takers are subcategorized into *risk lover, risk neutral, and risk averse* (Blake 2000). Traditional finance theory, applying assumptions of rational behavior, argues that the majority of people are risk averters, and hence “risk averse.” Given a choice of two investment opportunities with identical expected returns and uncertain but symmetrical probability distributions with different degrees of dispersion, i.e. risk, the less risky option is always selected by risk averters. Risk averters are said to have a declining marginal utility of wealth. A risk-neutral investor, in contrast, would be indifferent between the two options presented above, because the potential for a less favorable outcome than expected is exactly offset by the equal probability of a more favorable outcome. Finally, a risk lover would prefer the riskier choice because the utility conferred by a *financial* gain more than offsets the utility destroyed by a financial loss of equal magnitude. Under the above distribution assumption risk lovers, unlike risk averters, always have an increasing marginal utility of wealth (Tobin 1958).

According to traditional finance theory based on rational risk-averse behavior, a professional risk taker such as a firm manager or an entrepreneur differs from an individual investor or portfolio manager who is concerned with the preservation of wealth (capital) in real terms.
Professional risk takers apply their knowledge and expertise to gain exposure to a specific category, or categories, of largely nonsystematic business risk in which they believe themselves to have a competitive advantage. Such risk averters resemble the “plungers” described by James Tobin (1958) who have indifference curves that, although always upward sloping, may be either linear or upwardly convex. In contrast, wealth-preserving investors seek to diversify away nonsystematic risk exposure to retain only systematic risk that can then be managed according to their risk preferences. They achieve this by allocating their capital between many specialist professional risk takers—that is, by investing the capital in many firms and risky assets—hence delegating their nonsystematic risk decisions to firm managers. Tobin (1958) describes the second category of risk averters as “diversifiers,” and explains how the existence of plungers and the shape of utility functions are dependent upon the restrictions applied to the assumed probability distribution.

Frank H. Knight (1921) refers to risk as the quantifiable component of uncertainty in economic decision-making. However, John Maynard Keynes (1936) refers to “animal spirits” when he questions the foundations of neoclassical economics on the grounds that the risk-return trade-off implied by rational models of decision-making are difficult to implement in practice because risk is largely unquantifiable beforehand; furthermore, he argues that it is not possible to distinguish quantifiable risk from unquantifiable risk when making long-term investment decisions. Milton Friedman and Leonard J. Savage (1948) examine the implications for investors’ utility functions of the apparently contradictory behavior of individuals who purchase insurance contracts, accepting a certain small loss in exchange for avoiding the low probability of a big loss (risk-avoiding behavior), while at the same time purchasing lottery tickets with a negative expected return in exchange for the very low probability of a big gain (risk-seeking behavior). Subsequent work in behavioral finance, such as that reviewed by David Hirshleifer (2001) and Meir Statman (1999), argues that rather than the cold calculating behavior implied by neoclassical economics and traditional finance theory, many risk takers exhibit an optimistic bias, referred to as “overconfidence,” that may lead to risk-seeking behavior when faced with certain losses. Eddie Dekel and Suzanne Scotchmer (1999) discuss evolutionary explanations for risk-seeking behavior, citing the arguments of psychologists and evolutionary biologists to the effect that optimistic risk-seeking behavior exhibited by some individuals has allowed humans, as a species, to survive environmental shocks in which the expected value, and outcome, for the risk-averse majority would have been negative, and fatal.

RISK-RETURN TRADEOFF

The tradeoff between risk and return is one of the cornerstones of financial economics. When capital markets are in equilibrium, they determine a tradeoff between expected return and risk. The only way for investors to achieve a higher expected return is by taking on extra risk. This relationship between return and risk was first formalized by Harry Markowitz in 1952. In what later came to be known as the modern portfolio theory, he examined the tradeoff between risk and return in the context of the optimal selection problem for a portfolio of securities. In this theory investors aim to achieve the highest expected return for a certain level of risk; alternatively, they aim for the lowest level of risk for a certain expected return. An interesting graphical treatment of the risk-return tradeoff and variations in tastes for risk is given by James Tobin (1958).

Risk is measured as the standard deviation of the portfolio returns. This relationship is generally confirmed in total annual risk and return series. For example, over the period 1926 to 2002 stocks of small U.S. companies showed a mean return of 16.9 percent, stocks of large U.S. companies had a mean return of 12.2 percent, long-term government bonds had a mean return of 6.2 percent, and
Rites of Passage

short-term government bonds had a mean return of 3.8 percent. The standard deviations of the returns are in line with the realized returns, as they are 33.2 percent for the small stocks, 20.5 percent for the large stocks, 9.4 percent for long-term government bonds, and 3.2 percent for short-term government bonds (Ross, Westerfield, and Jaffe 2005).

The difference in returns between stocks and short-term government securities is generally referred to as the equity premium. In their 1985 work Rajnish Mehra and Edward Prescott questioned the high level of the equity premium. Their argument is that the size of the equity premium implies an unrealistically high degree of risk aversion on the part of the investors. Stephen Ross, Randolph Westerfield, and Jeffrey Jaffe, in their 2005 study, present an average equity premium of 8.4 percent over the period from 1926 to 2002. They also show that the premium was much lower between 1802 and 1870 (2.9 percent) and between 1871 and 1925 (4.6 percent). Ross, Westerfield, and Jaffe (2005) state that, because of the low-risk premiums in the historical data from 1802 to 1925, caution is needed in making assumptions about the current equity premium.

An important lesson from the theory of Markowitz is that, on the level of individual securities, the covariance between different securities is a more important risk measure than the variance of the individual securities. Securities that have a negative covariance with each other tend to absorb each other's risk. If the price of one of the securities goes down, the other goes up and vice versa. In the 1960s the portfolio theory of Markowitz was further developed into the capital asset pricing model (CAPM). According to this model, the contribution of a security to the risk of a large well-diversified portfolio is proportional to the covariance of the security's return with the market's return. The standardized contribution is the beta, which can be interpreted as the responsiveness of the security's return to that of the market. According to this model investors divide their wealth between the market portfolio of assets and the risk-free asset. They are allowed to hold short positions in either the market portfolio or the risk-free asset. The market portfolio consists of all risky investments in the economy. Therefore it does not only include shares of common stock, but also corporate bonds, real estate and more exotic investments such as wine and stamp collections. From a theoretical point of view, the CAPM has been criticized because it assumes a market portfolio the contents of which are not observable, thus making it impossible to test this model. Empirical research by Eugene Fama and Kenneth French in 1993 has shown that the responsiveness to the market is not the only determinant of the expected return of a security. Besides the earlier mentioned beta, their three-factor model includes two additional explanatory variables for security returns. These are the ratio of the market value of stock to the book value and the size of the company.

An important disadvantage of the use of the portfolio variance as the risk measure is that the variance is symmetrical. This means that it assigns the same weight to positive and negative deviations from the expected value. In other words, variance does not capture the common notion of risk as negative and undesired. The 2006 study by Chris Veld and Yulia Veld-Merkoulova of risk preferences of individual investors found that most investors use more than one risk measure. For those investors who systematically choose one risk measure, semivariance is most popular. This is also the case for stock investors, whereas bond investors favor the probability of loss as the most important risk measure.

**RITES OF PASSAGE**

A rite of passage is a series of rituals that conveys an individual from one social state or status to another—for example, from adolescence to adulthood, from single to married, from student to graduate, from apprentice to a full member of a profession, from life to death—thereby transforming both society’s definition of the individual and the individual’s self-perception. Such rituals of social transition mark culturally recognized stages of life and assist the individual and social group in adjusting to an individual’s new status and its implications for behavior and social relations. Transition rituals—rites of passage—
reduce the ambiguity associated with change, protecting individual psyches during the vulnerable period by reducing uncertainty and stress. Transition rituals are often directed toward the relationships between social conditions and physiological conditions (e.g., birth, puberty, marriage, pregnancy, death), demarcating certain points of the life cycle as especially significant. Ritual association of symbols and physiological processes provides a means of shaping and controlling human emotions and biological drives and then explaining them within wider cosmological frameworks.

Key social scientists who have studied rites of passage include Arnold van Gennep (1873–1957), who was the first to name and analyze them in 1908 in *Rites de Passage*; Bronislaw Malinowski (1884–1942), one of the first anthropologists to conduct on-site ethnography, who studied the functions of ritual on the Trobriand Islands off the coast of Australia; Victor Turner (1920–1983), who analyzed the roles of ritual and symbol among the Ndembu of Africa (1967, 1969); Mary Douglas (1921–2004, p. 8), whose work on symbols provided a profound understanding of their uses and effectiveness in ritual (1966, 1973); Clifford Geertz (1926–2006), whose *The Interpretation of Cultures* (1973) offers deep analysis of ritual’s roles in cultural preservation and revitalization; the biogenetic structuralists Charles Laughlin, John McManus, and Eugene d’Aquili (1979), who offer a neurologically based understanding of the effects of ritual and rites of passage; and Ronald Grimes, who explores first-person experiences of birth, initiation, marriage, and death (2000).

**STRUCTURE AND ROLES OF RITES OF PASSAGE**

Robbie Davis-Floyd defines ritual as “a patterned, repetitive, and symbolic enactment of a cultural belief or value” (2004, p. 8). Rituals usually work to enhance social cohesion, as their primary purpose in most cases is to align the belief system of the individual with that of the group. Ritual’s role in rites of passage is fourfold:

1. to give humans a sense of control over natural processes that may be beyond their control, by making it appear that natural transformations (e.g., birth, puberty, death) are actually effected by society and serve society’s ends (Malinowski 1954);
2. to “fence in” the dangers perceived cross-culturally to be present in transitional periods (when individuals are in-between social categories and therefore call the conceptual reality of those categories into question), while at the same time allowing controlled access to their energizing and revitalizing power (Douglas 1966);
3. to convey, through the emotions and the body, a series of repetitious and unforgettable messages to the initiate concerning the core values of the society into which he or she is being initiated through the carefully structured manipulation of appropriately representative symbols, and thereby to integrate those values, as well as the basic premises of the belief system on which they are based, into the inmost being of the initiate (Turner 1967, 1969; d’Aquili, Laughlin, and McManus 1979); and
4. to renew and revitalize these values for those conducting, as well as for those participating in or merely watching, the rituals through which these transformations are effected, so that both the perpetuation and the vitality of the belief and value system of the society in question can be assured (Turner 1967, 1969; Geertz 1973).

Rites of passage generally consist of three principal stages, outlined by van Gennep as: (1) separation of the individuals involved from their preceding social state; (2) a period of transition in which they are neither one thing nor the other; (3) a reintegration phase in which through various rites of incorporation they are absorbed into their new social state (van Gennep [1908] 1966). Van Gennep states that these three stages may be of varying degrees of importance, with rites of separation generally emphasized at funerals, and rites of incorporation at weddings. Yet, the most salient feature of all rites of passage is their transitional nature, the fact that they always involve what Victor Turner (1967, 1979) has called *liminality*, the stage of being betwixt and between, neither here nor there—no longer part of the old and not yet part of the new. In the liminal phase of initiatory rites of passage, “the ritual subject passes through a realm that has few or none of the attributes of the past or coming state” (Turner 1979, p. 237). Of this liminal phase, Turner writes:

The passivity of neophytes to their instructors, their malleability, which is increased by submission to ordeal, their reduction to a uniform condition, are signs of the process whereby they are ground down to be fashioned anew and endowed with additional powers to cope with their new station in life…. It is the ritual and the esoteric teaching which grows girls and makes men…. The arcane knowledge, or “gnosis” obtained in the liminal period is felt to change the inmost nature of the neophyte, impressing him, as a seal impresses wax, with the characteristics of his new state. It is not a mere acquisition of knowledge, but a change in being. (1979, pp. 238–239)

One of the chief characteristics of this liminal period of any rite of passage is the gradual psychological “opening” of the initiates to profound interior change. In many
Rites of Passage

initiation rites involving major transitions into new social roles, this openness is achieved through rituals designed to break down the initiates' belief system—the internal mental structure of concepts and categories through which they perceive and interpret the world and their relationship to it. Ritual techniques that facilitate this process include hazing—the imposition of physical and mental hardships (familiar to participants in fraternity initiation rites), and strange-making—making the commonplace strange by juxtaposing it with the unfamiliar. In The Reversible World (1978) Barbara Babcock describes a third such device, symbolic inversion, which works by metaphorically turning specific elements of this belief system upside-down or inside-out, so that the high is brought low, the low is raised high, and the world in general is thrown into confusion. The end result of this inversion, however, is usually that core cultural elements—values, practices, hierarchies—are in the end firmly returned to their positions of centrality, reverence, and weight. Yet, rites of passage can be used to completely overturn these core cultural elements, creating new societies and new religions.

For example, in studying the Moonies (followers of the Korean evangelist Reverend Sun Myung Moon), the sociologist Marc Galanter (1989) found that many of those who attended one of the five-day workshops ostensibly offered to explain the religion to interested newcomers ended up converting—even if their original reason for going was to learn enough about the religion to talk to a loved one into getting out. How could this happen? Participants sat through many hours of lecture, during which they were bombarded with an overload of confusing information, resulting in a narrowing of their cognitive abilities. Interspersed between lectures were periods of playful fun—volleyball, dancing—during which the newcomers were made to feel wholly important, wholly wanted, wholly loved. Allusions were made to Moon in connection with the Second Coming of Christ, and it was suggested that if newcomers were truly blessed, they might see visions of Moon himself during their regularly scheduled meditation periods. Not surprisingly, many did. Neuropsychologist John McManus explains:

As this process is continued over time, the cognitive reality model begins to disintegrate. Learned versions of reality and previously instrumental responses repeatedly fail the initiate. Confusion and disorganization ensue... at this point the individual should be searching for a way to structure or make sense out of reality, and in terms of the initiation, his search constitutes the launching point for the transformation of identity. (1979, p. 239)

The breakdown of their belief systems leaves initiates profoundly open to new learning and to the construction of new categories. Any symbolic messages conveyed to an initiate during this opening process can thus be imprinted on his or her psyche as deeply “as a seal impresses wax” (Turner 1979, p. 239).

TYPES OF RITES OF PASSAGE

Military initiation rites constitute a classic example of hazing, strange-making, and symbolic inversion. In the rite of passage of Marine basic training, the initiate's normal patterns of action and thought are turned topsy-turvy. He is made strange to himself: His head is shaved, so that he does not even recognize himself in the mirror. He must give up his clothes, those expressions of individual identity and personality, and put on a uniform indistinguishable from that of other initiates. Constant and apparently meaningless hazing (e.g., orders to dig ditches and then fill them up) break down his cognitive structure. Then through repetitive and highly symbolic rituals (such as sleeping with his rifle), his physical habits and patterns of thought are literally reorganized into alignment with the basic values, beliefs, and practices of the Marines.

Cross-culturally, the most prominent types of rites of passage are those dealing with life crises. They accompany what Lloyd Warner has called the movement of a man [sic] through his lifetime, from a fixed placental placement within his mother's womb to his death and ultimate fixed point of his tombstone ... punctuated by a number of critical moments of transition which all societies ritualize and publicly mark with suitable observances to impress the significance of the individual and the group on living members of the community. These are the important times of birth, puberty, marriage and death. (1959, p. 303)

The sequence of these life-crisis events that Warner uses refers to the baby's birth and not to the woman's giving birth, nor to her transition into motherhood. Thus, this sequence reveals a strong male bias that for many years influenced a general neglect within anthropological research and theory regarding the significance of women's rites across cultures. Arranged from a non–gender-biased perspective, the sequence would have to read: birth, puberty and coming of age, marriage, childbearing, menopause, death. (By now, female life transitions have been studied intensively by female anthropologists.) Additionally, for some cultures, we would have to add first haircuts, adolescent circumcision, debutante balls or quinceaneras, ritual scarring or tattooing, and other such to this list.
For example, in *Birth as an American Rite of Passage* (2004), Davis-Floyd analyzed obstetric procedures as rituals that convey the core values of the U.S. technocracy—a society organized around an ideology of technological progress—to birthing women. These core values center around science, technology, and institutions. The IV is the symbolic umbilical cord to the hospital, communicating to the laboring woman the powerful message that she is now dependent on the institution for her life. Likewise, the electronic fetal monitor (to which nowadays nearly all laboring women in developed countries are attached by means of two giant belts around their stomachs) serves as a powerful symbol of the cultural supremacy of science and technology—it makes the laboring woman dependent on a machine to help her produce her baby. The ability of symbols to imprint their messages onto an individual’s psyche is clearly expressed in the words of an interviewee, who said, “As soon as I got hooked up to the monitor, all everyone did was stare at it. Pretty soon I got the feeling that it was having the baby, not me” (Davis-Floyd 2004, p. 107). As this example shows, as an individual experiences the messages conveyed by a powerful symbol, her cognitive system can be partially or completely realigned around those messages. Whether the individual is giving birth, becoming an adult in the eyes of her society, undergoing a religious indoctrination, or being initiated into the army or a secret society, the ritual processes that constitute rites of passage are very much the same.

**RITUALS**

A ritual is a patterned, repetitive, and symbolic enactment of a cultural belief or value. Rituals usually work to enhance social cohesion, because their primary purpose in most cases is to align the belief system of the individual with that of the group. The more a belief system is enacted through ritual, the stronger it becomes; the less it is enacted, the weaker it becomes. For this reason, religious leaders often exhort their members to participate regularly—for example, to come to church every Sunday and to prayer group every Wednesday night. If people stop going, that is, if they cease to enact the religion’s rituals, over time that religion will have less and less meaning for them. Rituals are most commonly thought of as religious, but they can enact secular beliefs and values as effectively as religious ones.

A common misconception holds that ritual is something that goes on only in “primitive” cultures, whereas in so-called modern, developed societies, citizens benefiting from scientific enlightenment lead rational, de-ritualized lives. But the facts suggest otherwise. Across cultures and throughout history, all human cultures use ritual as the physical and psychological means for dealing with the mystery and unpredictability of the natural, social, and cosmic realms. Ritual’s cultural roles are myriad; they include engendering belief, maintaining religious vitality, stimulating economic exchange, enhancing courage, effecting healing, and transforming individual conscious-ness, often in order to bring it into alignment with group values as well as to intensify individual and group investment in social structure.

Robbie Davis-Floyd
CHARACTERISTICS OF RITUAL

Nine characteristics are integral to ritual’s myriad roles in human cultural life and constitute a sort of anatomy of ritual. They include:

1. the symbolic nature of ritual’s messages;
2. its embeddedness in a cognitive matrix (belief system);
3. ritual drivers—rhythmic repetition and redundancy;
4. the use of specific tools, technologies, and clothing;
5. the framing of ritual performances—their setting apartness from everyday life;
6. order and formality;
7. the sense of inviolability and inevitability that is established during ritual performances;
8. the acting, stylization, and staging that often give ritual its elements of high drama, and the fact that it is performed; and
9. often, a ludic dimension—the inclusion of play within the ritual frame.

Symbolism Ritual sends its messages through symbols. A symbol, most simply, is an object, idea, or action loaded with cultural meaning. Symbols are multivocal—that is, many meanings can be brought together and expressed in one symbol (e.g., a cross, a U.S. flag, a swastika). Unlike symbols, straightforward verbal messages are intellectually analyzed by the left hemisphere of the human brain, enabling the recipient to accept or reject their content. Symbols, in contrast, are received through the right hemisphere of the brain as a gestalt—that is, they are felt in the body and the emotions; their meanings are often internalized without conscious awareness. Objects or procedures can function powerfully as symbols even if the conscious intent of their performers is instrumental, not symbolic. For example, a blood-pressure cuff both records blood pressure and symbolizes western technocratic medicine, specifically the value it places on objective information; the stethoscope a physician wears around her neck both enables her to listen to a patient’s breathing and symbolizes her authoritative status. When a Marine basic trainee is required to sleep with his rifle, he “in-corporates” its symbolic meanings—they become part of his psyche through his body.

Because ritual works through symbols, the ritual process is fundamentally experiential, and the learning that takes place through ritual is experiential. Anthropological research on the difference between the experiential and didactic (explicit teaching) modes of learning has shown that experiential learning is by far the most powerful kind. Didactic learning can be intellectually rejected or easily forgotten, but experiential learning habituates the individual to specific patterns of behavior and response, and is much longer-lasting. It is no cultural accident that in contemporary society, as in the evolutionary past, skills, trades, and crafts, from tool-carving to eye surgery, have been taught experientially, through the process of apprenticeship.

A Cognitive Matrix A matrix (from the Latin mater, meaning “mother”), like a womb, is something from within which something else emerges. Rituals are not arbitrary; they come from within the belief system of a group. Each symbolic message that a given ritual sends manifests an underlying cultural belief or value embedded in that cognitive matrix. Sometimes these are made explicit in ritual, but quite often these deep beliefs that the ritual expresses are held unconsciously, rather than consciously. Ritual’s primary purpose is to symbolically enact and thereby to transmit a group’s belief system into the psyches of its participants, aligning their individual beliefs and values with those of the group.

Because the belief system of a culture is enacted through ritual, analysis of ritual can lead directly to a profound understanding of that belief system. For this reason, anthropologists studying various cultures often have focused on interpreting the rituals of that culture as a primary way to gain a deep understanding of it. In “Baseball Magic” (2000) George Gmelch decodes the rituals of baseball players to reveal their tensions, anxieties, and value system. Likewise, W. Lloyd Warner’s (1959) analysis of Memorial Day, “An American Sacred Ceremony,” shows how Americans use the rituals of this day to celebrate the unity of the nation in the face of its diversity, providing important insights into American life.

Ritual Drivers: Repetition and Redundancy For maximum effectiveness, a ritual will concentrate on sending one basic set of messages, which it will rhythmically repeat over and over again in different forms. What is repeated in ritual can include: (1) the occasion for its performance (as in a ceremony that happens every year at the same time); (2) its content (as in a chant); (3) the form into which this content is structured (as in a church ceremony); or any combination of these. This redundancy enhances ritual’s efficiency in communicating whatever messages it is designed to send; the Mayan farmer who hears the shaman chant the names of the gods twenty times in one hour; several times a day, is not likely to forget them.

Rhythmicity has long been recognized by anthropologists as a key feature of ritual. Rhythmic, repetitive stimuli affect the human central nervous system, generating (especially in safe, relaxed settings) a high degree of limbic arousal, coordinating emotional, cognitive, and motor
processes within an individual, and synchronizing these processes among the various ritual participants. This process of entrainment may be experienced as a loss of self-consciousness, a feeling of flow. Ritual entrainment can lead to transpersonal bonding, a sense of the unity and oneness of the group. This is a common experience at rock concerts—as the audience begins to entrain with the rhythms of the music, the huge auditorium suddenly seems to shrink and be suffused with shared energy; individuals feel like organic parts of a pulsating whole. Mickey Hart, the drummer for the rock group the Grateful Dead, said of this process, “Sometimes I felt that we were becoming a big noisy animal that made music when it breathed” (Hart, Stevens, and Lieberman 1990, p. 144).

Use of Tools, Technologies, and Clothing All rituals employ specific tools and technologies to achieve their purposes: altars and candles, the shaman’s drum and rattles, the priest’s robes and communion cup, the diviner’s tea leaves and tarot cards, the wrapped Christmas gift. From the Navajo hogan to the Internet, ritual technologies both construct the spaces within which ritual happens, and assist in effecting the external and internal transformations it achieves. As noted above, the technologies of ritual often fulfill both utilitarian and symbolic functions. The candle both sheds light and opens the doorway between dimensions; the communion cup both holds liquid and evokes the Last Supper. In healing rituals, the healer often perceives the patient through the medium of the technology (herbs, smudging, rattling, sandpainting in traditional cultures; x-rays, EEG printouts, vital-sign monitors in modern hospitals). As with much of everyday social life, humans mediate their experience through the technologies they create. This technological mediation influences our perceptions of reality in myriad ways. The technologies employed in ritual play a particularly significant role in altering and mediating perception and experience because their uses in the heightened, set-apart, and formalized structures of ritual make them especially effective at achieving the neural entrainment of the participants, en face or at a distance, with the rhythms of the ritual and with the symbolic messages it sends. The production, sale, and exchange of ritual artifacts serve as major economic drivers in all societies (Malinowski 1948).

Framing Rituals are framed, set apart from everyday life, often in spaces reserved solely for their performance such as churches, temples, theaters, sports stadiums, or simply the space in front of a home altar. This ritual framing works to ensure that participants will keep their attention focused on a limited stimulus field, facilitating their entrainment with the ritual’s symbolic messages.

Order and Formality In ritual events, things are no longer casual, but precise. Order matters, and the feeling is formal. Participants must pay special attention to body movements to be sure they are behaving appropriately, as in church or at a formal dinner. Order and formality—the careful sequencing of ritual performances—enhance the strength of this stimulus field and further work to set rituals apart from other modes of social interaction.

Inviolability and Inevitability Rituals establish an atmosphere that feels both inevitable and inviolate—the ritual must proceed to its conclusion through a pre-established sequence of events. Americans would find it hard to imagine, for example, stopping a graduation ceremony, interrupting the Pledge of Allegiance, or standing up in the middle of a church service to argue with the minister. Precise performance of ritual gives humans the feeling of setting into motion cosmic gears—an inviolable process that will inevitably propel the individual through danger to safety. Thus, ritual enhances courage. The anthropologists Sally Falk Moore and Barbara Myerhoff (1977) suggested that ritual’s insistence on repetition and order evokes the perpetual processes of the cosmos, thereby metaphorically implying that the belief system being enacted has the same permanence and legitimacy as the cosmos itself.

Performance: Acting, Stylization, and Staging Like a play, ritual is performed, often giving it an element of high drama. The more dramatic ritual is, the more effectively it engages the emotions. These qualities enable ritual to command the attention of participants and audience, while at the same time serving to deflect questioning and the presentation of alternative points of view. A major part of ritual’s job is to imbue participants with a strong sense of the value, validity, and importance of the belief system being enacted; in so doing, ritual must also work to preclude challenges to that belief system. Those who manipulate and control ritual are powerful performers, from traditional shamans to Jerry Falwell and Adolf Hitler. Ritual experts have both total command of the belief system being enacted, and dramatic, often charismatic, flair. Their effectiveness rests on their ability to entrain groups, to reorder divergent individual cognition around the symbolic matrix they represent. Hitler’s ability to accomplish this through ritual was so profound that within a few years he was able to restructure the cognitive system of an entire nation around the symbolic matrix of German dominance and Aryan supremacy, represented by one powerful symbol, the swastika. On a smaller scale, the continued survival of many indigenous cultures often depends in large part on the ability of their shamans to dramatically and inspirationally perform the rituals that enact and thus perpetuate their unique cultural values, beliefs, and sense of
connectedness to place. When the shamans die without transmitting this cultural lore to apprentices who can carry on, the culture is well on its way to extinction, or at least profound alteration.

A Ludic Dimension In spite of its serious formality, ritual often has an intensely ludic (playful) dimension. In some cultures, such as the Mescalero Apache of New Mexico described by anthropologist Claire R. Farrer (1991), during their most sacred ceremonies a clown mimics and mocks the singers as they perform the ritual acts in the required sequence, while the watching participants laugh uproariously at his antics. The Mescalero do not feel that their laughter decreases the sacredness of the event; on the contrary, it increases it through the revitalizing energy that laughter brings to the culture’s most deeply held beliefs. A parallel can be found in the rodeo clown. Rodeo bull riders ritually display the manly heroic virtues that their subculture holds dear; the clowns, whose task it is to divert the bulls while entertaining the audience, mock those manly traits even as they themselves exemplify them.

THE EFFECTS OF RITUAL
The primary effects of ritual include:

1. the cognitive transformation of its participants that is ritual’s primary purpose;
2. the cognitive simplification that ritual works to engender in its participants by rendering complex ideas more straightforward or unitary, which can generate habituation;
3. the cognitive stabilization that ritual can achieve for individuals under stress, which can include the enhancement of courage;
4. the preservation of the status quo in a given society; and
5. ritual’s paradoxical effectiveness at facilitating social change.

Although not every ritual achieves each of these purposes, these are all part of the capacity of ritual as a symbolic form. Ritual is a powerful didactic and socializing tool. To grasp its inner workings is to have a choice in our response to the rituals that permeate our daily lives, and of which we are often unaware.

Cognitive Transformation Belief follows emotion. In general, people are far more likely to remember events, and to absorb lessons from those events, if they carry an emotional charge. Ritual generates that charge—it focuses the emotions on the symbolic messages it presents. This focusing process is enhanced by the rhythmic repetition of the ritual’s messages, which will often intensify toward a climax. If the ritual is successful, belief will be generated through the mapping-on process. And because of the emotions associated with that belief, neither the experience nor the belief will be forgotten.

For example, in Juan the Chamula (Pozas 1962), a Chamula Indian from highland Chiapas in southern Mexico describes a healing ceremony in which the shaman attempts to cure him of “soul-loss” through a long and elaborate ceremony. At the climax, the shaman twists the neck of a rooster and kills it, and Juan exclaims, “suddenly I felt free!” (p. 90). This experience of ritual healing constituted for Juan an important step in his cognitive reintegration into the cultural system he had left years ago, and to which he was now returning. As this example demonstrates, healers can use ritual’s ability to generate belief to map their interpretation of the illness into the mind-body of the patient. When these fuse, healing can be achieved, as the body responds to what the mind now believes.

The emotional affect generated by ritual can do much more than generate belief. Humans have two nervous subsystems, the excitation and the relaxation systems. Usually, when one is discharging, the other is quiescent. But their repeated stimulation may cause both to simultaneously discharge. Under conditions of stress, the sensations so produced are more likely to be those of calm, reassurance, and a sense of control. Under stable social and environmental conditions, this simultaneous discharge of both nervous systems produces an intensely pleasurable, almost orgasmic sensation—indeed, both subsystems do simultaneously discharge during orgasm. This ecstatic state occurs in ritual when physical, emotional, and intellectual experiences of the symbolic messages become one. It may be very brief, experienced only as, for example, goose bumps popping out as the bannering-bearing choir marches down the aisle on Easter Sunday, or a shiver down the back as you salute your national flag during a parade. It may happen only once during the ritual, or may be repeated at numerous focal points. Or this ecstatic state may be prolonged, as in meditation and religious trance or dance. In any case, these ecstatic sensations become experientially associated by ritual participants with the belief system enacted in the ritual. Charismatic Christian groups are filled with the Holy Spirit; !Kung bushmen trance-dancers with the boiling energy they call ni/um. Biological research has established that during this state, high levels of endorphins—natural pain-relieving, pleasure-producing chemicals—flood the central nervous system. This ritually induced experience of ecstasy is one of the most powerfully emotion-filled experiences available to humans. Once they experience this state (especially the prolonged version) during a ritual, they are likely to want more. This desire can be a powerful incentive to
begin regular attendance at the ritual events that can induce and consistently reproduce these feelings.

Through the ritual drivers of rhythmic repetition, evocative style, and precise manipulation of symbols and sensory stimuli, collective rituals focus the emotions of participants on the calculated intensification of their messages. Ritual generates intense emotion, even ecstasy, in humans, and intense emotion, in turn, generates belief (d’Aquili, Laughlin, and McManus 1979).

Transformation for ritual participants can be both mental and physical. It can be external in the eyes of society, and/or internal in the psyche of the participant. Some kind of transformation can be said to occur in all types of ritual—even a simple ritual greeting opens a previously nonexistent channel of communication between two individuals, resulting in almost immediate entrainment of their bodily rhythms. Deep transformation for ritual participants occurs when the symbolic messages of ritual fuse with individual emotion and belief, and the individual’s entire cognitive structure reorganizes around the newly internalized symbolic complex. Although this process may sound final, as if it could happen only once, it is not. Human neural structures are not made of cement; they are relatively fluid. As most religious adherents know from experience, belief waxes and wanes, and must be continually reinforced through ritual if it is to retain a significant role in shaping individual cognition and behavior. Each time a person attends a religious service or a political rally, he or she can experience this process anew, diving deeper and deeper into the symbolic constellations of belief of the religious or political system.

The most profoundly transformative of all rituals are initiatory rites of passage and religious indoctrinations. These break down the belief system of the initiate, then rebuild it around the beliefs and values of the group—a conversion experience. Whether the individual is converted to Islam or Christianity, or initiated into the army or a fraternity, the ritual process is very much the same.

**Cognitive Simplification** In any culture, ritual participants will differ from each other both in intellectual ability and in cognitive structure. Straightforward didactic communications must take these differences into account if their messages are to be understood. But ritual must work collectively, for the masses. Ritual overcomes this problem by working to reduce its participants, at least temporarily, to the same cognitive level, at which they will all see the world from within the confines of one cognitive matrix. An individual thinking at this level will tend to see the world in terms of black and white, interpreting others as either with her or against her (as do religious fundamentalists, for example). This sort of either/or thinking does not allow for the consideration of options or alternate views. The advantage of this reduction of ritual participants to univariate thinking is that a single ritual structure is now sufficient to communicate social norms and values to a wide variety of individuals. This process is most clearly visible in the performance of religious rituals such as the Catholic Mass, which can be deeply and equally convincing to individuals of all levels of cognitive complexity, or in the political rallies of totalitarian regimes such as Nazi Germany. Such cognitive simplification must precede the conceptual reorganization that accompanies true psychological transformation. The most common technique employed in ritual to accomplish this end is the rhythmically repetitive bombardment of participants with ritual’s symbolic messages.

The order and precision of ritual, combined with its repetitious nature, can be highly effective athabituating individuals to doing things one way only. Physicians have described how their learning process was channeled into a “narrow riverbank” in which the water can only flow one way; one said, “You do it, and you do it, and you do it some more” (Davis-Floyd and St. John 1998, p. 54). Habituation to this one way can be efficient; it can also preclude openness to new and perhaps better ways.

**Cognitive Stabilization** When humans are subjected to extremes of stress, they are likely, at least temporarily, to retrogress cognitively into a dysfunctional condition in which they become panic-stricken, unreasonable, or simply out of touch with reality. Whenever the danger of such retrogression is present, ritual plays a critical role, because it stabilizes individuals under stress by giving them a conceptual handle-hold to keep them from losing it. When the airplane starts to falter, even those who do not go to church are likely to pray! The simple act of rhythmically repeating, “Dear Lord, please save us,” can enable terrified passengers to avoid the panic behavior that might increase the likelihood of disaster.

Ritual stands as a barrier between cognition and chaos by making reality appear to fit accepted cognitive categories—that is, by making the world look the way it ought to. In other words, to perform a ritual in the face of chaos is to restore conceptual order. Even a small semblance of order can enable individuals to function under the most chaotic of conditions. The earthquake victim sweeps off her front steps when the entire house lies in ruins around her. This behavior is not as irrational as it seems at first glance. Those steps represent one ordered cognitive category, and for the householder, to make them clean is to ground herself in a little piece of the known and the familiar. From that cognitive anchor, she can then begin to deal, a little at a time, with the surrounding chaos.
To perform a series of rituals is to seek to induce a particular outcome, often involved with creating a sense of safety in the presence of danger. The Trobriand sea fisherman who makes elaborate offerings and incantations in precise order before embarking into perilous waters believes that, if he does his part correctly, so must the gods of the sea do their part to bring him safely home. For the same reasons, the batter turns his cap backwards and clutches his rabbit's foot before he steps up to the plate. And the Bolivian tin miner, before descending into the hot and dangerous mines that he thinks of as the devil's territory, makes an offering of candy or tobacco to the devil so that the devil will be obliged to reciprocate by protecting him. In such cases, the rituals provide a sense of control that gives individuals the courage to act in the face of the challenge and caprice of nature. But the inevitability of ritual can be a double-edged sword: Rituals do not always work, and the sense of confidence they generate can be a false one. Nevertheless, that sense of confidence does facilitate action in the face of fear.

Rituals—from prayer, to carefully setting the table, to lighting candles for loved ones in danger—provide their participants with many such cognitive anchors. Ritual thus has high evolutionary value; it was a powerful adaptive technique our hominid ancestors most likely utilized to help them continue to function at a survival level whenever they faced conditions of environmental or social stress. Groups that believe together can act together to meet and overcome crises and danger. When belief is not shared, joint action is much more difficult to achieve. Even warring armies often rely on a number of shared beliefs, symbols, and rituals—the Red Cross or Red Crescent of medical facilities, the white flag of truce, the process of formal surrender. These are rituals of stabilization that can work even in the face of the mayhem of war.

**Preserving the Status Quo** Through explicit enactment of a culture's belief system, ritual works both to preserve and to transmit that belief system, and so becomes an important force in the preservation of the status quo in any society. Thus one usually finds that those in power in a given social group strive to maintain control over ritual performances. They utilize ritual's tremendous power to reinforce both their own importance and the importance of the belief and value system that sustains them in their positions.

**Effecting Social Change** Paradoxically, ritual, with all of its insistence on continuity and order, can be an important factor not only in individual transformation but also in social change. New belief and value systems are most effectively spread through new rituals designed to enact and transmit them. Even if a ritual is being performed for the very first time, its stylistic similarities with other rituals make it feel tradition-like, thus giving entirely new belief systems the feel and flavor of being strongly entrenched and sanctioned by ancient practice. Moreover, entrenched belief and value systems are most effectively altered through changes in the rituals that enact them. Indeed, ritual represents one of society's greatest potentials for the kind of revitalization that comes from internal growth and change in response to changing circumstances.

**BIBLIOGRAPHY**

*Robby Davis-Floyd*
ROBESON, PAUL
1898–1976

Paul Robeson, an African American actor, singer, and social activist, was born on April 9, 1898, in Princeton, New Jersey, and died on January 23, 1976, in Philadelphia, Pennsylvania. During the 1930s and 1940s, Robeson gained international renown as a concert singer and stage actor. His embrace of the Soviet Union and communism, however, especially during the formative years of the Cold War and the backlash against left-wing causes during the 1950s, effectively ended his artistic career and contributed to his physical decline.

Robeson was the youngest of five children. His father, William Drew Robeson, was born a slave in North Carolina, but he escaped and went on to become a Presbyterian minister in New Jersey, until he was forced to leave his congregation over a major dispute. Robeson’s mother, Maria Louisa Bustill, hailed from a prominent Philadelphia family and became a schoolteacher. She burned to death tragically in a house fire when Robeson was only six years old, an experience that undoubtedly affected the youngster.

Between 1916 and 1919, Robeson attended Rutgers College in New Jersey as the only African American student. While there, he gained both academic and athletic distinction, being elected to Phi Beta Kappa and twice named an all-American football player. Between 1920 and 1923, he attended Columbia Law School in New York City, playing professional football on weekends and acting to pay the bills.

It was at Columbia University that Robeson met chemistry student Eslanda Cardoza Goode (1896–1965). Her grandfather, Francis L. Cardozo (1837–1903), was trained as a teacher, minister, and carpenter, and served between 1868 and 1872 as the first black person elected to state office in the history of South Carolina. Robeson and Eslanda married in 1921 and had their only child, Paul Robeson Jr., in 1927. Eslanda went on to become an anthropologist and journalist, as well as her husband’s manager and life-long partner until her death.

After graduating from law school, Robeson turned his back on a legal career because of the limited opportunities afforded qualified African Americans. This decision was to prove momentous because it resulted in the launching of one of the most gifted and committed artistic lives of the twentieth century. Robeson’s career embraced theater, music, and film. During the early 1920s, he worked with the Provincetown Players based in Greenwich Village and earned praise for his roles in playwright Eugene O’Neill’s The Emperor Jones (1920) and All God’s Chillun Got Wings (1924). In 1930 he appeared opposite renowned British actress Peggy Ashcroft (1907–1991) in a London production of Shakespeare’s Othello and in 1932 a Broadway version of Jerome Kern’s musical Show Boat (1927). Despite his glittering stage success, not everyone was impressed. The Trinidadian writer and activist C. L. R. James (1901–1989) saw Robeson play Othello in Broadway in 1943 and declared: “Robeson was rotten. He is a magnificent figure, a superb voice, and, as usual with him, at moments he is overwhelming. But in between his lack of training, his lack of imagination, were awful” (1996, p. 90).

Robeson also gained fame as a concert singer and recording artist. Both Robeson and his longtime pianist and arranger Lawrence Brown (1893–1972) played an important role in performing and disseminating African American spirituals and folk songs throughout the United States and Europe. As such, the duo belongs to a black Atlantic musical tradition stretching back to the Fisk Jubilee Singers of the 1870s. It is important to note, however, that their recorded spirituals revolutionized such music by allowing the voice to be free from the performer.

Robeson’s third artistic arena was film. During the 1930s, the film industry embarked upon a major transformation with the advent of sound and mass audiences. Robeson appeared in about a dozen American and British films between 1933 and 1942, including The Emperor Jones (1933), Sanders of the River (1935), Show Boat (1936), and The Proud Valley (1941). Although his characters often challenged existing racial stereotypes portrayed on the silver screen, these films also reinforced stereotypes about subservient and comedic black people and the benefits of Western colonialism. Robeson later expressed regret over some of these films, a regret the modern viewer can appreciate.

Between 1927 and 1939, Robeson and Eslanda sojourne in Europe. These were important years for Robeson’s development as a black artist because they
exposed him to the international communist movement, as well as Pan-African and anticolonial politics. While living in London, Robeson and his wife undertook the study of African history, politics, and languages. At the same time, Robeson participated in the West African Student’s Union and became acquainted with a younger generation of Caribbean and African leaders, such as C. L. R. James and George Padmore (1903–1959) of Trinidad, Jomo Kenyatta (1890–1978) of Kenya, and Nnamdi Azikwe (1904–1996) of Nigeria. It was this milieu that encouraged Robeson’s “return” to Africa. This spiritual rather than physical return encouraged Robeson to espouse a set of universal values that included, rather than derided, the importance of African culture to world historical development. It was a position familiar to many black abolitionists of the nineteenth century and recognizable in some of the more sober statements of modern Afrocentrists.

The other important component of Robeson’s political development concerned international socialism. The Great Depression had destroyed many people’s lives and corroded their faith in capitalist democracies. In contrast, the new Union of Soviet Socialist Republics (USSR) promised a more equitable distribution of resources, constitutional guarantees of the equality of all people regardless of nationality or race, and international solidarity. In 1934 Robeson made the first of numerous visits to the USSR, eventually learning Russian and schooling his son there for several years. At the same time, Robeson became involved in socialist and pacifist causes, including performing benefit concerts for Republican troops fighting against the fascist takeover in Spain. Although some black radicals, such as Padmore and Richard Wright (1908–1960), saw irreconcilable differences between communism and Pan-Africanism, others like C. L. R. James and Robeson envisioned new connections between the two ideologies.

On his return to the United States, Robeson continued his artistic endeavors, as well as his commitment to numerous left-wing and anticapitalist causes. In the gathering hysteria of the cold war, however, Robeson was to experience serious state and civil obstacles. Although never a member of the Communist Party, officials in both Sacramento and Washington, D.C., accused Robeson of being a communist. In 1950 the U.S. State Department revoked his passport, keeping it until 1958. An invitation for him to appear at a musical festival in Peekskill, New York, sparked white vigilante violence and resulted in scores of injured people, while both Broadway and Hollywood blacklisted him. Despite this, Robeson continued performing at black churches and small functions sponsored by radical groups. He also continued his radical politics. In 1951 Robeson, on behalf of the Civil Rights Congress, submitted a petition to the United Nations titled “We Charge Genocide,” detailing 153 killings, 344 crimes of violence, and numerous other human rights abuses against black citizens in the United States during the previous six years. This tactic of exerting international pressure on the United States stretched back to the proposed building of an antislavery wall, a project advocated by Frederick Douglass (1818–1895) and others during the mid-nineteenth century.

After regaining his passport, Robeson and his family moved to Europe. The persecution and blacklisting, however, began to take its toll. Robeson moved in and out of hospitals in the Soviet Union and Europe, and in 1961 he had a nervous breakdown and attempted suicide. In 1963 the Robeson family returned to the United States. After Eslanda’s death in 1965, Robeson moved to Philadelphia to live with his sister. A year later he made his final public appearance at a benefit dinner for the Student Nonviolent Coordinating Committee. During a seventy-fifth birthday tribute at New York’s Carnegie Hall, which he could not attend because of ill health, Robeson sent a message declaring that he was as “dedicated as ever to the worldwide cause of humanity for freedom, peace, and brotherhood.”

Scholars have debated Robeson’s historical significance. Was he an idealist whose adherence to the Communist Party made him, in the words of critic Harold Cruse, “a great potential spokesman with a misdirected and ineffective political line” (1967, p. 297)? Or was he an important radical social democrat who played a critical role in propagating popular front culture from the 1930s through 1950s as argued by Michael Denning (1996)? Or was he, as Sterling Stuckey (1987) claims, primarily a black cultural nationalist who brilliantly fused African and black American cultural activities? Interested readers, especially young artists, should read, hear, and see more about Robeson’s remarkable life and make up their own minds. Paul Robeson’s true significance concerns his obvious artistic talent; his consistent support for antiracist, anticolonial, and international liberation struggles; and his commitment to a radical political and cultural tradition. In today’s world, we can imagine Robeson challenging the iniquities of globalization, demanding peace in the Middle-East, and insisting on racial justice for all.

ROBINSON, JOAN
1903–1983

Among the great scholars who made significant contributions to economics in the twentieth century, one could say that there were scores of men but only one woman who really stood out. Of course there were well-respected female economists of the time, such as Mary Marshall (1850–1944) and Ursula Hicks (1896–1985), but for bravado none of them trumped Joan Violet Morris Robinson. She was swift, sharp, and influential. To her friends, admirers, and students, she was gentle, caring, and encouraging. To those who saw in her a menacing adversary and detractor, she was rude, ruthless, and inconsiderate. While she was at home or abroad, whether lecturing or listening, her presence was noticed.

Joan Robinson was born in Surrey, England, and was first educated in London. She then entered the University of Cambridge for economics, where she graduated in 1925. She married the economist Austin Robinson in 1926. Although she traveled extensively throughout the world, her heart remained in Cambridge, site of her home and her university position and where she died in 1983.

As an economist, Joan Robinson was not only a theorist and pragmatist but her knowledge and interest in history, a subject she had studied before economics, afforded her a good grasp of politics and world affairs. She was truly a complete social scientist who believed that knowledge and theory should be the handmaidens of policymaking. Two words could encapsulate the driving motivation for her research and leftist political persuasion: economic justice. Whether in her preoccupation with unemployment in the making of John Maynard Keynes’s General Theory of Employment, Interest, and Money (1936), with the disparities of classes in her version of Marxian economics, or with economic development in her writings on China and India, she was compassionately engaged by all aspects of income distribution.

In her sixty-three-year academic career, Joan Robinson published 378 books, articles, and other writings, all noted in a bibliography compiled by Maria Cristina Marcuzzo (1991). There are numerous writings about Joan Robinson, the most notable being the enormous two volumes edited by George R. Feiwel and published in 1989. The collection’s essays, some critical, some laudatory, are of particular interest because their contents highlight reactions from economic theorists across the whole spectrum in relation to Joan Robinson’s philosophy, methodology, macroeconomics, and economic theory and specifically the notions of equilibrium, time, capital and growth, and unemployment and the theories of general equilibrium, trade, imperfect competition, games, credit markets, and finance. On reading the various essays, one could not conclude that Joan Robinson had an answer to every theoretical issue, but she touched a sensitive chord for many foundational premises of economics.

For economic-theory purists, The Economics of Imperfect Competition (1933, 1969) places Joan Robinson in the pantheon of economists. For economists in general, her work on employment and interest and especially The Accumulation of Capital (1956, 1969) was the catalyst to the highly charged Cambridge Capital Controversy, which pitted Joan Robinson and Pierro Sraffa of Cambridge, England, against Robert Solow and Paul Samuelson of Cambridge, Massachusetts, among others. Joan Robinson voiced opposition to the claims of the dominant neoclassical economics for the universality of its theory of production. Her critique, which targeted the “circularity” of the neoclassical interrelationship of capital value and interest rate, pushed economists of every stripe to ponder the relevance and logic of the production function, disembodied technical change, labor-capital substitution, relative prices, and capital accumulation, among other concepts, and led to a fruitful period of intense debate. Put simply, proponents of the Capital Controversy claimed to have shown that the neoclassical explanation of factor payments and substitution and to some extent growth is restrictive, only valid in a world of constant capital-labor ratio. For die-hard Robinsonians, a subgroup of post-Keynesians, for whom she was in battle with the foundations of neoclassical economics, Joan Robinson will forever remain a Joan of Arc.

**PRIMARY WORKS**

ROCK 'N' ROLL

Rock 'n' roll, a hybrid popular musical form that emerged in the United States in the early 1950s, became one of the most important cultural forces around the world. Rock 'n' roll began when musicians mixed black rhythm and blues with Southern white country and gospel musics, helping to spark a cultural revolution in the 1950s and 1960s. The first exhilarating blasts of rock 'n' roll defied the Eisenhower era's puritanical emphasis on social and political conformity. This interracial music, edgy and rebellious, broke down social barriers by challenging sexual, racial, and, later, political taboos. The music made a powerful statement that young Americans were less divided by race than their parents.

During the 1950s white musicians such as Bill Haley, Elvis Presley, Buddy Holly, and Jerry Lee Lewis and black musicians such as Chuck Berry, Little Richard, and Fats Domino created rock 'n' roll; often fast and highly danceable, it posed a challenge to urban pop music from Tin Pan Alley and rural-oriented country music. Haley took rhythm and blues songs and reconfigured them for a white teen audience. Influenced by the electric blues, Berry created the distinctive rock 'n' roll guitar style. Presley, known as "Elvis the Pelvis" because of his suggestive, hip-swinging performances, became the first rock superstar, aided by skillful marketing. American rock 'n' rollers also developed a large following in Britain and Europe.

Rock 'n' roll evolved into rock in the early 1960s and became the heart of that decade's youth movement. American society in the 1960s grew to be deeply divided over the war in Vietnam, protest movements against racism and sexism, and "countercultural" youth who flouted social norms. In 1963 the Beatles began a "British Invasion"—a wave of U.K. rock groups, such as the Rolling Stones and the Kinks—that electrified American audiences and energized rock. "Beatlemania" reached around the world, spawning local imitators and spreading new fashions. The Beatles revolutionized recording technology and matured from top-selling pop stars to musical philosophers; many of their later albums, such as Sgt. Pepper's Lonely Hearts Club Band (1967), are infused with deep meaning. Bob Dylan, once a folk singer, wrote poetic songs exploring the human experience, including politics. The probing music of Dylan, the Beatles, and the musicians they influenced played a major role in protest and social movements. New rock styles also emerged. Hence, the Byrds and Crosby, Stills, and Nash created country rock and folk rock, while the Beach Boys expanded the boundaries of Southern California–based surf music. Often inspired by drug experiences, San Francisco musicians like the Jefferson Airplane and the bluesy Janis Joplin created psychedelic rock. The innovative guitarist Jimi Hendrix laid the foundation for heavy metal and hard rock. The merging of rock music, political protest, and the counterculture of disaffected youth led to the Summer of Love in 1967, when thousands congregated in San Francisco, and culminated in the Woodstock Music Festival of 1969, when 300,000 rock fans crowded a New York farm.

By the early 1970s several rock icons (including Hendrix and Joplin) had died, the war in Vietnam had wound down, protest movements had faded, and a more conservative social and political environment had emerged in the United States. New rock-derived styles developed over the next four decades. In the United States and especially Britain, punk music—loud, fast, and anarchic—appealed to alienated working-class youth with its frontal assault on prevailing social and political values. Heavy metal, with its deafening guitars, was angry and often obsessed with sex and violence. In contrast, dance musics such as disco, techno, and rave were escapist. But some rock musicians directly addressed social and political issues. The superstar Bruce Springsteen, mixing rock and folk, criticized U.S. foreign policies and the neglect of the working class and poor. In the 1990s punk and heavy metal were combined into a new style, grunge, most prominently represented by the Seattle group Nirvana. By the twenty-first century rock had fragmented into diverse styles with niche audiences.

African Americans created popular musics influenced by rock. The soul music of the 1960s, from artists like James Brown and Aretha Franklin, conveyed a message of black self-respect and unity parallel to the civil rights movements. The slickly produced Motown sound appealed to both blacks and whites. Beginning in the
1980s rap, an eclectic urban mix of African American and Caribbean traditions, became the most cutting-edge, politicized music, sometimes called the CNN of the black ghetto. The boastful, angry lyrics highlighted conflict between black and white, rich and poor, male and female. Like rock, rap was adopted by alienated groups around the world, but in the United States its radical message was watered down by the twenty-first century. Whether rock and its kindred musics were empowering or diversionary, promoting social and political change or helping maintain the status quo, remained subject to debate. Whatever the case may be, these debates reflected the enduring appeal of musics rooted, despite five decades of changes, in the black-white fusion of early rock 'n' roll.

RODNEY, WALTER

1942–1980

Walter Rodney was born on March 23 in the colony of British Guiana and educated at Queen's College in the capital, Georgetown, and the University of the West Indies in Jamaica where he gained a First Class Honors BA degree in history. Rodney grew up during the country's anticolonial movement; his father was a member of the Marxist-oriented People's Progressive Party, which led the struggle for freedom from British rule. Rodney went on to complete his doctoral dissertation, titled "A History of the Upper Guinea Coast, 1545–1800," at the University of London in 1966. He taught at the University of Dar es Salaam in Tanzania during the period of radical political and agrarian reform led by Julius Nyerere.

TEACHING CAREER

Tanzania was the headquarters of the Organization of African Unity's Liberation Committee, and Dar es Salaam became the base for many of the exiled liberation move-

ments of Southern Africa. Among these organizations were the African National Congress of South Africa, Frente da Libertação de Moçambique (FRELIMO) of Mozambique, and Movimento Popular da Libertação de Angola (MPLA) of Angola. In this atmosphere Rodney developed his Pan-African perspectives along Marxist lines and sided with Southern Africa's left-wing activists.

He returned to Jamaica to teach at the University of the West Indies in 1968. His radical views and association with Rastafarians and the Black Power movement in Jamaica led to Rodney being banned from reentering Jamaica by the government after he attended a Black Power conference in Canada in October 1968. The demonstration of university students together with Kingston's urban youth against the ban marked a watershed in Jamaica's political development; the scale of mass action in support of Rodney surprised the regime. There were protests throughout the Caribbean, and in Tanzania, Canada, and London. Rodney's reputation as a scholar-activist with a relevant critique of the Jamaican and Caribbean post-colonial elites was firmly established. In the nearly ten months in 1968 that Walter Rodney spent in Jamaica he not only taught but also spoke to groups in the slums of Kingston and in the rural areas. He had an extraordinary ability to speak with and listen to working people and unemployed youth. He explained the significance of Africa to Caribbean history and the importance of the struggles against the racial and social legacies of slavery and colonialism. His articles and speeches embodying these positions were published in the book The Groundings with My Brothers (1969).

HOW EUROPE UNDERDEVELOPED AFRICA

Rodney returned to lecture at the University of Dar es Salaam from 1969 to1974. In 1972 he published his best-known work How Europe Underdeveloped Africa. This work brings together historical scholarship and development theory to argue that the transatlantic slave trade and European and North American capitalist slavery did serious damage to Africa in depriving it of millions of its young people from the sixteenth to nineteenth centuries. Rodney was also critical of the impact of colonialism in retarding the development of the continent. The book is more than protest literature in that it advances a revolutionary humanist view of development and decolonization at a time when many countries on the continent were achieving political independence, a process that was also under way in the English-speaking Caribbean whose territories were populated largely by descendants of African slaves.

Some scholars argue that Rodney relies too heavily on the dependency theory of the 1960s and How Europe
Underdeveloped Africa has been criticized for not looking sufficiently at the internal factors in Africa that accounted for the slave trade and African underdevelopment. Ironically, however, much of his early work had focused on internal factors that retarded Africa's development and Rodney's analysis of Africa's traditional elites was caustic. So in a sense How Europe Underdeveloped Africa was a departure and the emphasis on European involvement in the hugely profitable trade completed his treatment of the relationship between European slave traders and plantation owners on the one hand and on the other hand Africa's elites who facilitated the slave trade. Also in 1972, Oxford University published Rodney's doctoral thesis A History of the Upper Guinea Coast 1545–1800. In 1975 two chapters titled “The Guinea Coast” and “Africa in Europe and the Americas” were published in the Cambridge History of Africa. The latter essay was a pioneering study of the African Diaspora.

A HISTORY OF THE GUYANESE WORKING PEOPLE, 1881–1905

Walter Rodney returned to his native country, now called Guyana, in 1974 and was denied a job at the University of Guyana by President Forbes Burnham. Burnham saw the young scholar-activist as a political opponent and hoped to keep him out of Guyana. Rodney was associated with the Working People's Alliance, a political organization that sought to offer a nonracial approach to Guyanese politics in a country where party politics had been divided between Cheddi Jagan's East Indian–based People's Progressive Party and Forbes Burnham's African-based People's National Congress. Between 1974 and 1980, when he was murdered at age thirty-eight by a booby-trapped walkie-talkie given to him by a member of Guyana's Defense Force, Rodney lectured in the United States and Europe for short periods in order to ensure an income. He continued his research and completed working on A History of the Guyanese Working People, 1881–1905, which was published posthumously in 1981. This work embodies his philosophy on the creative role of ordinary people in the making of history and introduces the contribution of African slaves to the humanization of the Guyanese coastal environment in creating “an elaborate system of canals ... to provide drainage, irrigation, and transportation” (Rodney 1981, pp. 2–3) in a remarkable transfer of Dutch technology to a coastal landscape that was below sea level. It was the first book on the Guyanese working people written in the twentieth century. In 1982, the book won the American Historical Association's Albert J. Beveridge Prize and in 1983 the Association of Caribbean Historians gave Rodney a posthumous award.

Rodney's reputation as a historian of the Caribbean was duly recognized. He harnessed history in the service of African and Caribbean decolonization with a view to giving his readers a sense of their creative capacity to build postcolonial societies. The Barbadian novelist George Lamming, in his foreword to A History of the Guyanese Working People, 1881–1905, described Rodney's approach to history as “a way of ordering knowledge which could become an active part of the consciousness of an uncertified mass of ordinary people and which could be used by all as an instrument of social change. He taught from that assumption. He wrote out of that conviction” (Rodney 1981, p. xvii).

Rodney was also a gifted and compelling speaker whose arguments were backed up by a mastery of contemporary data. He possessed a capacity to communicate complex ideas to small study groups and large audiences with great clarity drawing on his solidly rooted knowledge of African and Caribbean history.

ROE V. WADE

Few U.S. Supreme Court rulings have been as contentious as the Court's 1973 decision in Roe v. Wade. This landmark decision not only invalidated a number of state abortion laws, it also served to further divide public opinion with respect to “discretionary” abortion decisions (Franklin and Kosaki 1989, p. 759).

A number of states reformed their abortion statutes to broaden access to legal abortions in the late 1960s. Some of these laws, for example, permitted abortion when a woman's health was in danger as opposed to only her life. Some reforms, moreover, provided for legal abortions if a woman had been a victim of rape or incest, as well as in situations in which a fetal defect was present (Tribe 1991, p. 42). Of course, prior to Roe, a number of states,
including Texas, prohibited abortions except when a woman's life was in danger.

In addition to a perceived need for further abortion law reform, developments in the Supreme Court's privacy doctrine with respect to the use and distribution of contraceptives provided constitutional arguments that could potentially be applied to the expansion of abortion rights (Nossiff 2001, p. 41). In *Griswold v. Connecticut* (1965), the Supreme Court held that a Connecticut statute prohibiting the use of contraceptives violated a married couple's constitutional right to privacy. In *Eisenstadt v. Baird* (1972), the Court recognized that single persons also enjoy a right to privacy with respect to reproductive decisions when it struck down a Massachusetts law banning the provision of contraceptives to unmarried persons in order to prevent pregnancy.

The legal question as to whether a woman's privacy right could extend to her decision to terminate a pregnancy was presented to the Supreme Court in *Roe v. Wade*. Jane Roe, who would later reveal her identity as Norma McCorvey, was pregnant and wanted to obtain an abortion in Texas, her state of residence. Texas law, however, prohibited abortions except when necessary to preserve the mother's life. McCorvey's pregnancy did not threaten her life, nor did she have the finances to travel to a state in which abortion was legal. A Dallas attorney referred McCorvey to Sarah Weddington and Linda Coffee, two attorneys who were preparing a legal challenge to the Texas abortion laws. The case, which eventually became a class-action lawsuit, also involved a married couple dubbed John and Mary Doe. They argued that the law interfered with their marital relationship since Mary's physician had cautioned her about becoming pregnant but directed her to refrain from using birth control pills because of a medical condition. Under Texas law, however, abortion would be a foreclosed option for the couple in the event of an unintended pregnancy. James Hallford, a physician who was charged with violating the Texas abortion laws, also participated in the lawsuit. The plaintiffs sought a declaration that the Texas laws were unconstitutional, as well as an injunction to prevent their enforcement (Weddington 1992, pp. 50–62).

Jay Floyd, representing the Texas Office of the Attorney General, raised important challenges concerning the plaintiffs' standing to sue and the timing of the lawsuit. With respect to the merits, he argued that there was no constitutional right to an abortion and that the state had a “compelling interest in protecting the fetus” (Weddington 1992, p. 66). The representative for the district attorney's office argued further that abortion was an appropriate area for state regulation and also suggested that the privacy interests of women seeking abortions must give way to the protection of the unborn (Weddington 1992, pp. 65–66).

Although the three-judge trial court agreed with Floyd's argument that John and Mary Doe did not have standing to sue, the court held that Roe and Hallford could pursue their claims. On the merits, the court found that the laws violated the constitutional right of individuals to determine whether they wanted children; however, it refused to issue the plaintiffs' request for an injunction. Dallas County district attorney Henry Wade's assertion that he would continue to enforce the contested law assisted Weddington's efforts in obtaining a Supreme Court review of the decision (Weddington 1992, pp. 67–69).

The Supreme Court first heard oral arguments in *Roe* in 1971. However, the justices agreed that the case should be reargued to allow newly appointed justices William Rehnquist (1924–2005) and Lewis Powell (1907–1998) to take part in the decision. Accordingly, the Court issued its landmark decision in 1973. Writing for a seven-member majority, Justice Harry Blackmun (1908–1999) argued that a constitutional “right of privacy … is broad enough to encompass a woman's decision whether or not to terminate her pregnancy.” (410 U.S. 113, 153). However, the majority also recognized that the state has legitimate interests with respect to “health,” “medical standards,” and “potential life” that might justify regulating abortion at certain points (410 U.S. 113, 154).

Specifically, Blackmun articulated a trimester framework to evaluate when these state interests could justify regulation of a woman's decision to have an abortion. During the first trimester of a woman's pregnancy, when the risk of mortality from an abortion is low relative to the risk of childbirth, the Court held that “the abortion decision … must be left to the medical judgment” of a woman's doctor (410 U.S. 113, 164). However, by the second trimester, the state could regulate abortions in order to protect maternal health (410 U.S. 113, 163). Finally, the state's interest in protecting “potential life” could justify regulation when the fetus reaches the stage of viability, defined as the point at which it has “the capability of meaningful life outside the mother’s womb.” At this stage, Blackmun held that the state could prohibit abortion so long as exceptions were made “to preserve the life or health of the mother” (410 U.S. 113, 154).

While many individuals and groups defended the Supreme Court's decision in *Roe*, others criticized the ruling in the hope of seeing it limited or overruled. At the state level, for example, attempts to restrict access to abortion have been made through laws requiring parental or spousal notification or consent, informed consent, waiting periods, and tests to determine fetal viability, as well as through laws prohibiting public financing or assistance
for abortion procedures (Nossiff 2001, p. 148; Trible 1991, p. 144). McCorvey herself later backed away from her affiliation with the Roe decision and the pro-choice movement. In 1995 McCorvey was baptized by the national director of Operation Rescue, a well-known organization opposing abortion rights in the United States (New York Times 1995, p. A12), and in 2003 she unsuccessfully petitioned a federal court to reconsider the result announced in Roe (New York Sun 2003, p. 6).

The battle over abortion rights and the Roe decision has also colored the Supreme Court judicial selection process. Nominees to the Court after Roe have been scrutinized concerning their positions on privacy rights generally and their opinion of Roe specifically. Although John Roberts was tapped to replace Chief Justice Rehnquist in 2005, particular concern was raised that Justice Sandra Day O’Connor’s replacement in 2006, Samuel Alito, might provide the Court with the votes needed to overrule this controversial decision. However, as legal analyst Jeffrey Toobin (2005, p. 81) noted, a number of Republican-appointed justices have joined the Court since Roe, and, although the Court has revisited the topic of abortion rights in a number of cases, it has yet to overrule the decision.

ROLE CONFLICT
The term role conflict refers to a clash between two or more of a person’s roles or incompatible features within the same role. These incompatibilities can consist of differing expectations, requirements, beliefs, and/or attitudes. The term role relies on the theatrical metaphor of an actor performing his or her part in a staged play. Although stage actors generally play only one character per play, the same actor will go on to play multiple characters throughout his or her career, and different actors often play the same role in different ways. Unlike theatrical actors, people in everyday life enact multiple roles simultaneously. For example, Jane might be a boss, an employee, a daughter, a mother, and so on. Often, these roles are activated concurrently and harmoniously. Jane’s role as the primary wage earner for her family is not likely to be in conflict with her role as a supervisor at work. Different roles are sometime incompatible, however, and the requirements of one role can clash with those of another. In addition, contradictory requirements within the same role can produce role conflict.

There are two types of role conflict: intrarole conflict, referring to incompatible requirements within the same role, and interrole conflict, referring to clashing expectations from separate roles within the same person. Intrarole conflict can arise in two ways. First, different people sometimes have inconsistent conceptions concerning the requirements and expectations that constitute a particular role. Jane’s conception of being a good mother might consist of having a job outside of the home. She might also believe that providing socioemotional support to her family is a necessary ingredient in her role as a mother. However, Jane’s mother-in-law might think that to be a good mother Jane would need to relinquish her job to provide around-the-clock care for her children. Because of these differing conceptions concerning the role of a mother, Jane is likely to experience intrarole conflict.

Intrarole conflict can also occur when the role itself has contradictory expectations or requirements. Jane might feel that her role as a mother requires her to provide emotional warmth to her children. The same role might also require her to discipline her children following misbehavior. Because being sensitive and supportive is at odds with enacting discipline, Jane is likely to experience intrarole conflict in situations where her children misbehave. To resolve intrarole conflict, the role can be compartmentalized. In her role as mother, Jane might justify her job outside the home by noting that it allows her to care for...
her children financially. Working outside the home provides them with groceries, housing, heat, schooling, medical care, and so on. As such, it fits with Jane’s conception of the motherhood role. An additional way to resolve intrarole conflicts is to avoid those who define a role differently. As such, Jane might avoid her mother-in-law because of their clashing conceptions concerning the motherhood role.

Interrole conflict arises when the requirements and expectations of one role interfere or conflict with those of another role. Jane’s role as mother is likely to conflict occasionally with her role as a worker employed outside the home. When one of her children becomes ill, Jane may find that the demands of her job (e.g., staying at work) are in conflict with the demands of motherhood (e.g., taking her child to the doctor). There are a number of ways to resolve interrole conflicts. Often, people will prioritize their roles. In some situations, such as when an important deadline looms at work, it may be more important for Jane to stay late at work. In this situation, her role as a worker will take priority over her role as a mother. At other times, such as when her children are ill and in need of care, her role as mother will take priority. We can also compartmentalize different roles. For example, Jane may find that she interacts with others very differently at work and home. By compartmentalizing her roles, she can be task-oriented in her role as a boss, but socioemotionally oriented in her role as wife and mother. Roles can also be specialized. If children need to be disciplined, Jane and her husband can develop a system in which her husband is in charge of discipline while Jane is in charge of providing warmth and comfort.

The experience of role conflict has been associated with negative health, psychological, social, and work-related outcomes. Role conflict is positively correlated with experienced stress level and depression and negatively correlated with self-esteem. In the workplace, role conflict is negatively correlated with job commitment, job involvement, participation in decision-making, and satisfaction with compensation, coworkers, and supervision and, as Mary Van Sell, Arthur Brief, and Randall Schuler (1981) observed, positively associated with job dissatisfaction, on-the-job tension, and intentions to leave an organization.

ROLE MODELS

A role model is an individual who is perceived as exemplary or worthy of identification or imitation. It is a conscious or unconscious emotional attachment not necessarily involving direct personal contact; for example, identification with sports or entertainment figures is common. Mentors, a subset of role models, deliberately support, guide, and shape younger or less experienced individuals as they weather difficult periods, enter new arenas, or undertake challenging tasks. Mentoring may include elements that are instrumental (e.g., career advice, networking contacts, financial assistance) and psychosocial (e.g., emotional support, companionship). Having a role model or mentor is a commonly identified protective factor contributing to resilience—that is, successfully responding to challenges or overcoming adversity—and mitigating risk, particularly in ethnic minority adolescents experiencing poverty or familial dysfunction.

Role model selection reflects critical elements of psychosocial functioning and self-perception, particularly ethnic identity. Individuals generally identify sociodemographically similar role models, and socioeconomic status (SES) is associated with having a role model. In a study of a representative sample of Los Angeles adolescents, African American teens almost exclusively chose African American role models (96%), whereas two thirds (64%) of Latinos chose an ethnically congruent model. Overall, 75 percent of Latinos chose a role model of color, with 11 percent having chosen African Americans. Four in five whites identified a white role model. About one in five teens chose relatives as role models, the most common choice. Whites were more likely than African Americans or Latinos to have known extrafamilial role models. Lower SES and being male were associated with selecting a figure role model available primarily through the media, as opposed to a known individual. Consistent with these findings, a qualitative study found that the type of role model (family member or figure) most often identified by low-income African American males differed in high school and college samples: Identified role models for the college students were primarily, though not exclusively, family members (Taylor, 1989). Extrafamilial models tended to be ethnically similar to the young men. Enduring and substantive role models were less frequently identified in the high school sample than in the college sample. Still, even as subjects of fleeting interest, African
Americans—mainly entertainers and political or religious figures—were most often chosen. Regarding the other primary sociodemographic characteristic, gender, boys are more likely than girls to choose a gender-congruent role model. This difference is only found for the figure category of models. For known role models, boys and girls choose same-sex or opposite-sex persons at about the same rate. The greater availability of powerful male figures in the popular media and in sports, in particular, and the greater status that our society affords to men may explain this finding.

That learning occurs through observation and imitation or modeling of revered others has been well established by social learning theorists. For example, a parenting study demonstrated that teen fathers often come from families in which there were role models for teen parenthood; for example, first-time teen fathers were three times as likely to have older brothers who were themselves teenaged parents. Certainly, the effectiveness of role models in encouraging the adoption of commercially desirable but risky behavior (e.g., cigarette smoking and alcohol consumption) is well known to the advertising industry. Commercial marketing utilizes inspirational and aspirational role models in product “branding” and sales promotion. Inspirational role models are quite similar to the target audience (“people like us”); social distance is minimal and “cultural” values and traditions are shared, thereby increasing motivation and enhancing self-efficacy. Peer modeling, in which youth or adult lay health advisors (promotoras) are used in outreach, embodies this construct. In contrast, aspirational role models have culturally valued attributes that are coveted by but less prevalent in the targeted population, for example, a higher position within a work hierarchy, extraordinary athletic or musical talent, or physical attractiveness.

The evidence for the utility of role modeling is growing. Evidence that suggests the positive influence of ethnically matched role models may be seen in the educational persistence of graduates of historically black colleges and universities. Although only one in five African American undergraduate students are enrolled in these institutions, one in three black college graduates hail from these institutions, as do more than half of those earning doctorates and more than two thirds of all black professionals. Several recent empirical studies also support the positive influence of role models on certain measures of resilience in ethnically diverse and, particularly, high-risk adolescent populations. This influence may operate largely by enhancing ethnic identity among African American, Latino, and Native American youths. Having a role model, particularly one known to the adolescent, has been linked to higher self-esteem and academic performance, decreased substance use, fewer behavioral problems in school, higher levels of physical activity, and lower levels of engagement in early or high-risk sexual activity. Extrapolated known role models were just as positively influential as family members. Even a figure role model is associated with some lowered risk, though they exert less influence than known role models. Ethnic congruence of role models does not seem to affect outcomes, but because it is apparent that adolescents for whom ethnicity is most salient strongly gravitate to role models of the same ethnicity, sufficient variability to test this hypothesis is unlikely to be found.

Many young people do not have role models or mentors. Exposure of low SES ethnic minority youngsters, in particular, to positive role models and adult images of their own ethnicity—a task previously performed by racially segregated but socioeconomically heterogeneous churches, neighborhoods, and schools—is increasingly recognized as critical to their development of a stable identity. Social service programs of many varieties have been developed to address this gap through, for example, faith-based organizations, schools, government programs, and unaffiliated community-based efforts. One-to-one mentoring (e.g., Big Brother/Big Sister, center-based programs at YMCAs/YWCAs and Girls’/Boys’ Clubs) is a common programmatic approach to providing this resource. However, these programs place tremendous time and energy demands on mentors, who also face their own family demands and often professional struggles with discrimination. Thus, there is limited availability of appropriate one-to-one mentors, given the scarcity of volunteers and increasing socioeconomic homogeneity of ethnic minority neighborhoods. School-based “career day” programs, another common approach, present useful opportunities for role modeling. They do not, however, provide the continuity and personalization of contact necessary for a sustaining influence. Small-scale self-image-enhancement approaches that directly or indirectly utilize role models have been used with measurable success with high-risk African American and Latino youth, and are integral parts of many community institutions. Such emerging “hybrid” role-modeling or mentoring interventions (e.g., many culturally grounded “rites-of-passage” programs) are less taxing to volunteers than one-to-one involvement, but offer more consistent and personal contact than “career days.”

Positive images and examples of ethnically diverse individuals of both genders are needed. Attention should be directed to developing and systematically evaluating innovative and cost-effective approaches, both stand-alone programs and programs in conjunction with the provision of other services, via media or in person. Feasible and effective interventions to expose youth to appropriate role models are early in their development, and the process by which youths identify role models is not well understood. Because the process of selecting and
emulating a role model provides critical—and potentially socially constructive—access to the self-images of young people, progress in this area is central to advancing the field of adolescent health promotion.

ROLE OVERLOAD

SEE Role Theory.

ROLE THEORY

Role theory is generally concerned with explaining the relationship between the individual and society. It has guided empirical research on a range of topics, including the structure of interaction in small groups, the maintenance of gender differences, the development of commitment to deviant behavior, the genesis and resolution of conflict in organizations, and the construction of personal identity. Although the development of role theory has occurred primarily within sociology, it originated in several different social science disciplines. The first significant contributions were published in the 1930s with independent work by the anthropologist Ralph Linton (1893–1953), the psychotherapist Jacob Moreno (1889–1974), and the social philosopher George Herbert Mead (1863–1931). Of these three, Mead’s contributions have been the most significant as he was an important influence on the emerging new discipline of sociology. Within sociology, there have been two distinct traditions of role theory; these have been nominally categorized as the structural and interactionist schools.

THE STRUCTURAL SCHOOL

Starting in the 1950s and continuing through the 1960s, role theory was associated mostly with the work of the American sociologist Talcott Parsons (1902–1979). During this period, Parsons and his associates were developing a comprehensive theory of society that came to be known as structural functionalism. Under structural functionalism, society is viewed as a complex system of structures and processes with layers of interconnected subsystems, institutions, values, positions, and roles. In Parsons’s scheme, the role concept is used to explain how individual desires and motivations are reconciled with the collective needs of society. This occurs in part through the process of socialization, where kinship, educational, and religious institutions transmit societal values. When individuals are properly socialized, they fulfill the expectations and needs of an orderly social system by playing the roles associated with their position in society. Parsons argued, for example, that the preponderance of men in the occupational system of the 1940s was functional in that it eliminated competition for status between husband and wife. While the husband achieved status through his role as provider in a high-prestige job, the wife achieved a functionally equivalent status in her role as homemaker where prestige could be achieved through superiority in personal appearance, house furnishings, and other artistic pursuits.

In the structural tradition, roles are typically defined as the socially shared expectations and behaviors associated with a position in society. Because individuals have multiple positions in society, however, there are times when role expectations pull in competing directions so
that fulfilling one role may mean failing to fulfill another. This dilemma has been called role conflict, and it can take several different forms. One of these is role overload, which occurs when there is not enough time or energy to play all the roles in one's role set. Related structural interpretations of role theory have been concerned with differentiating among the different types of roles, describing changes in roles, and explaining why people often deviate from role expectations.

THE INTERACTIONIST SCHOOL
By the middle of the 1960s a competing version of role theory was in development. The so-called interactionist school emerged initially as a critique of the dominant structural perspective. The interactionist critics argued that the structural approach to role theory put too much emphasis on societal consensus, relied naively on the existence of widespread conformity with social norms, and held an overly mechanical and deterministic view of social behavior.

The American sociologist Ralph H. Turner spearheaded the development of the interactionist approach by introducing the idea of role making. According to Turner, in everyday situations there is always a degree of uncertainty and discretion. Since roles can only suggest general patterns of action, individuals must cooperate to create and modify roles in particular settings. Research has shown this to be true even in strict, hierarchical organizations such as the military and correctional institutions, where positions are rigidly defined and rules are enforced within a clear authority structure. From the interactionist perspective, understanding the process by which individuals learn to coordinate their actions and construct role-related behavior is crucial.

The central idea in the coordination of joint action is a process called role taking, a concept developed in the seminal work of Mead. Role taking, sometimes called taking the role of other, occurs when an actor anticipates the behavior of others in specific situations and adjusts his or her action accordingly. This uniquely human ability develops along with language and other basic skills of symbolic interaction. Once in place, a capacity for role taking enables mutual understanding, coordinated action, and the development of common plans. It is also fundamental to the more complex process of building and maintaining large social institutions. Thus, in contrast to the top-down structural approach to role behavior that focuses on role playing, the interactionists present a bottom-up approach that stresses the creative aspects of role making.

INTEGRATION
After the 1980s, differences between structuralists and interactionists gave way to more synthetic approaches where ideas from both theoretical traditions were integrated. Thus, there developed a general acknowledgment that social roles can profoundly limit and structure patterns of social behavior while at the same time they can serve as resources for enabling and facilitating other actions. Rather than emphasizing role playing or role making, it became more productive to see roles as social resources that are deployed by institutions and persons in different ways; in short, the emphasis was now on role using.

Although role theory is no longer central to most comprehensive theories of society, as it was for Parsons and Mead, it does continue to generate a stream of work at different levels of analysis. At the social psychological level, for example, scholars have found that social roles are central components of one's overall identity, and evidence shows that roles have profound influence on people's behavior in social settings, on how they organize and process information, and on their political, economic, and moral priorities. At the macro and institutional level, research has documented the increasing proliferation of new, more specialized roles in modern society as well as the changing nature of traditional roles resulting from economic and cultural globalization.

ROLE USING
SEE Role Theory.

ROLL CALLS
Roll calls are votes taken by a legislative chamber in which the names of legislators are recorded along with their votes
on a question. Rules and practices surrounding roll call votes vary across legislatures because of differences in constitutions, chambers rules, actions of legislative leaders, political cultures, legislature sizes, and the technologies used to record votes. Because they are highly visible, roll call votes are useful to social scientists who research legislative behavior. Techniques used to study roll call votes range from simple descriptions to sophisticated scaling techniques adapted from psychometrics and econometrics.

The most thoroughly studied roll call record is that of the U.S. Congress. Article I, section 5 of the U.S. Constitution requires that “the Yeas and Nays of the members of either House on any question” shall be entered in the journal upon the demand of one-fifth of those present. Through the end of the 109th Congress (2006), the U.S. House of Representatives and Senate together had recorded nearly 94,000 roll call votes.

The first social scientific use of roll call votes is attributed to A. Lawrence Lowell’s 1902 essay “The Influence of Party upon Legislation in England and America.” Lowell introduced the idea of the “party vote,” defined as a vote in which at least 90 percent of one party in a legislature voted against at least 90 percent of the other party. An important extension of Lowell’s idea was suggested by Stuart Rice in 1928 through his “index of cohesion” and “index of likeness.”

Efforts by the liberal interest group Americans for Democratic Action (ADA) in the 1940s encouraged the use of roll call votes to summarize the voting tendencies of individual legislators. The ADA began publishing an annual list of “key votes” in Congress, reporting how often each member of Congress (MC) supported the ADA position. These reports allowed one to array MCs along a continuum, ranging from the most liberal, with a “liberal quotient” of 100 percent, to the most conservative, at a quotient of 0 percent. Ever since the ADA pioneered this technique, dozens of groups have developed “support scores” that reflect their own agendas.

Interest-group support scores are easy to calculate and intuitive to understand, but they have serious shortcomings. Interest-group ratings tend to be based on a small number of roll call votes, thus discarding the rich information that the omitted roll call votes can provide. The roll call votes chosen are typically unusually divisive, which causes the resulting ratings to be too extreme. These techniques also require a priori agreement about which votes best reveal the underlying ideological dimension being described.

Beginning in the 1980s social scientists started exploring ways to overcome these deficiencies, taking advantage of advances in measurement theory and computational capabilities. A frequently used example of this is a class of techniques pioneered by Keith Poole and Howard Rosenthal, called NOMINATE (for Nominal Three-step Estimation). NOMINATE scores can be constructed from a large number of roll call votes analyzed simultaneously across a long period of time. Ratings from such techniques as NOMINATE show that a single left-right ideological dimension underlies most roll call behavior across American history, that a second dimension of choice sometimes emerges that corresponds to race-related issues, and that individual legislative voting behavior is highly stable over time.

ROMA, THE

The term Roma has come into common parlance to refer to all the populations in Europe (and indeed the rest of the world) that used to be referred to in their host societies as Gypsies, Cigány, Tsigan, and other terms. It thus covers a number of populations with particular histories but also certain distinctive commonalities. This article focuses on those who have a historical link to populations that have spoken Romani, an Indic language now in use on all the continents of the world. Speakers of an ancestral form of Romani were in all likelihood among a number of populations of service nomads who circulated in the southern ranges of the Eurasian landmass between northern India and the Middle East over the past thousand years or more. Other related ethnic-linguistic groups include the Dom (speakers of Domari), found across the Middle East, and the Lom (speakers of Lomavren, spoken in Armenia, Georgia, and eastern Turkey).

The reconstruction of the early history of Romani-speaking populations is fraught with difficulties as archival records are scant. Moreover the procedure by which earlier historians attempted to reconstruct early modern Romani social life from philological materials is
now widely discredited. Genetic evidence (mitochondrial and Y-chromosome DNA) unsurprisingly supports the linguistic link to North India, but founder effects and other sampling uncertainties mean detailed and datable population histories cannot as yet be reconstructed.

While all Romani speakers can be called Gypsy, not all Gypsies are Romani speakers. Nevertheless, there are some signs of a broader Roma ethnic awareness developing in some circles, at least across Europe, including people whose ancestors may never have spoken any Indic language.

On the basis of dialect differentiation it is possible to distinguish four large segments of the European Romani population. The four branches of Romani are Balkan, Vlax (centered in Romania but spreading westward), Central, and Northern. British or Welsh and Iberian Romani once constituted independent branches but survive only as special lexicons used as part of English or Spanish.

These linguistically determined regions of diffusion indicate zones of greater and more intense interaction among Romani speakers but cannot be used to determine the movements or settlement history of all Roma. Since the dialect groupings mentioned here are more or less territorially based (even if the boundaries between them are loose and alterable), dialect corresponds to some extent to history. It thus makes heuristic sense to talk, for instance, of Sinte (in Germany), of Gitanos (in Spain), or Vlax (in various parts of Europe and beyond) as loosely defined cultural groups within the Roma.

Roma speak Romani (often spelled Romany) or Romances. This is an Indic language, probably originating in central India over one thousand years ago. Yaron Matras has estimated that in the early Romani inherited lexicon, of 1,000 lexical roots, 200 to 250 are from Greek, around 70 from Iranian, and 40 from Armenian, leaving about 650 to 700 roots of Indic origin. There are no monolingual speakers of Romani, and the language as spoken by Roma in different parts of Europe incorporates loan words reflecting the history of local contact with other languages. The fact that the term Gypsy and other exonyms such as the Hungarian Cigány or the German Zigeuner are found from the late Middle Ages in Europe indicates a likely time of arrival for Romani speakers. These exogenous terms are more or less abusive and have strongly negative connotations of deceit and laziness.

Roma make up approximately 3 to 5 percent of the population of most eastern European countries as well as of Spain. Exceptional cases (Poland and the Baltic States, for example, where Roma represent tiny minorities) are areas where Nazi-led persecution and killings were particularly intense. In the early industrialized west of the Continent, Roma or Gypsies constitute around .1 percent of the total population.

Scholarly dispute rages as to the reasons for the persistence and success of the Roma way of life. For some, this is simply a matter of the fall of the cultural dice. The ability of Roma groups to retain a distinctive set of values and then to remain relatively unnoticed and unknown has been stressed by one school of anthropologists. Another focuses on the particular ways Roma have resisted assimilation into sedentary societies and the ways they have constructed cultural values in an oppositional strategy to peasant and farming communities.

The traditional Roma economic orientation was strikingly differentiated from that of the surrounding agricultural population, known by Roma as gázé or “farmers.” Though there are communities of Roma who own land, most tend not to rely directly on the natural environment for their livelihood. Rather, they depend on human environments. Thus Roma are found wherever the non-Roma environment provides them with the human resources they need to carry out their economic activities.

In early modern Europe, Roma were known as blacksmiths and musicians, both “infamous” professions that were construed as either polluting or socially dangerous. For much of the twentieth century successful Roma engaged, if possible, in various forms of trade, especially with antiques, horses or other animals, and (more recently) secondhand cars. Poorer Roma are often engaged in various forms of scavenging of industrial waste goods that are then sold back to the gázé (non-Roma).

For most Roma, trade provides an insufficient income to support a family, and so wage labor in factories became the norm after World War II, at least in Spain and Eastern Europe. Under communist rule all citizens were obliged to have a registered workplace. The collapse of the planned economies and with them the heavily subsidized and profoundly inefficient and unmodernized industries of the region led to mass unemployment among Roma families across the region, especially elder Roma. Rates of unemployment are estimated at between 30 and 70 percent in many of the former communist countries.

Relations between Roma and the authorities do not always reflect directly the state of Roma’s economic position. The relationship between Roma and majority populations has by no means always been conflictual, though issues around sedentarization and resistance to proletarianization have recurrently led to periods of persecution.

Eighteenth- and nineteenth-century policy toward Gypsies was largely driven by police concerns that they represented a hard-to-identify, unsettled population, and the origin of extraterritorial police (such as Interpol) procedures in Europe lies in part in police work dealing with Roma in Germany and other areas of central Europe.
history of Roma in the principalities of Wallachia and Moldavia is of particular note, as many were enslaved to feudal lords and monasteries until the mid-nineteenth century. Slavery here refers to a form of unbreakable personal and domestic bond rather than the more familiar plantation slavery characteristic of the Americas in the eighteenth and nineteenth centuries.

During the 1930s persecution of Roma across central and eastern Europe intensified, in particular inside the German Third Reich. Using anthropological and, more importantly, police procedures for identifying “the unsettled,” the Third Reich registered the entire German Romani population before deporting two-thirds to camps in the occupied east. Although the Nazis never formulated an explicit “final solution” for the Roma, the cumulative effect of sterilization programs in the Third Reich, mass deportations to Auschwitz, and systematic massacres on the eastern and southeastern fronts constituted a genocidal campaign in which well over 100,000 Roma died.

For forty years after the war the democratic German successor state failed to fully acknowledge the nature and extent of the Nazi persecution, and thousands of Roma died without receiving proper reparation or compensation for their suffering. This remains a potent symbol to young activists of the marginalization of Roma in European political and civic society.

Historical work has demonstrated the existence of a sharp sense of persecution and discrimination among Roma as early as the eighteenth century. But it was not until the second and third decades of the twentieth century that any serious attempts at local and international self-organization began. Communist nationality policy tended to blow alternately hot and cold on Romani self-organization, but the legacy in Bulgaria and Hungary of political movements in the 1950s can still be felt. The formation of the International Romany Union in 1971 counts as a formal landmark in the process of Romany self-organization, but perhaps more important has been the emergence of a broadly based Romani intelligentsia across eastern Europe since the early 1970s. In the early twenty-first century scores of young Romani intellectuals are shaping a new, Europe-wide Romani movement. The presence, in 2007, in the European Parliament of two young Romani members, Lívia Jároka and Viktória Mohácsi (both from Hungary), is indicative of the dynamism of this new generation.

Government policies toward Roma vary widely across Europe. In the former communist countries a certain policy schizophrenia may be observed: encouraging an ethnicization of public policy (with programs targeted not at social problems but ethnic groups) and at the same time a tendency to represent the so-called Roma question as one of national security, playing on fears of demographic exploitation among Roma and demographic collapse of the majority population. In reality Romani demographic trends mirror the decline in fertility witnessed across Europe.

Mass mobilization of Roma has been hampered by a number of factors. In most Romani communities social organization is kinship based, with no formal political structures existing over and above loose networks of related families. Romani communities tend to be extremely egalitarian in values, despite economic inequalities among households being marked. This militates against the emergence of stable political leadership. Occasionally “kings” or other forms of traditional leaders arise when non-Gypsy authorities collaborate with prominent Roma to control access to some limitable resource, but the authority of such people is largely contingent on their ability to “serve up” the non-Gypsies.

In the last two decades of the twentieth century the importation of a human and civic rights discourse through mainly U.S.-based nongovernmental organizations (NGOs) has provided an oppositional language of self-representation to activists. With most of the former communist countries now inside the European Union (EU), the U.S.-backed NGOs tend to be withdrawing. At the same time EU structures tend to encourage a demand for participation and collaboration at a local level with community representatives. It remains to be seen whether the imported oppositional stance of civic rights can be adapted to the needs and opportunities of the new situation. It is in this complex context that the new, highly educated young Romani elite are trying to create a politics of Romani identity fit for the twenty-first century.

ROMAN CATHOLIC CHURCH

The Roman Catholic Church refers to the worldwide assembly of Christians who are in full communion with the pope, the bishop of Rome, who is regarded as the sign and instrument of Catholic unity among bishops and faithful alike. Statistically, Roman Catholics form the largest single Christian body, with close to 1.1 billion members worldwide. The rise of Christian culture in western Europe is virtually synonymous with the history of the Roman Catholic Church.

Although other Christians sometimes refer to themselves as catholic (from the Greek word meaning universal or complete), Roman Catholics believe communion with the See of Rome is required for full membership in the Catholic Church. In addition to the Western or Latin Rite Catholics, there are some 20 million Eastern Christians in full communion with Rome (better identified as Eastern Catholics than Roman Catholics).

Roman Catholics believe the pope is the successor of Peter, appointed by Jesus Christ as the chief apostle and head of the Church. By the late second century, Irenaeus, the bishop of Lyon (c.130–200), saw agreement with the Church of Rome as necessary for all Christian churches.

Following persecutions by various Roman emperors, the Church received legal recognition from Constantine in 313. The move of the imperial capital from Rome to Byzantium (Constantinople) in 330 set the stage for the later split (schism) of the Byzantine Church from the Church of Rome in 1054.

The monasteries of the Church preserved learning after the collapse of the Roman Empire. The rise of Islam in the seventh century and the Muslim invasions of Spain and Gaul prompted the pope to form an alliance with Charlemagne and the Franks. The Crusades (1095–1291) failed to maintain Christian control over Jerusalem and stem the eventual spread of Muslim power into Asia Minor (Turkey).

During the Middle Ages (c. 800–1400), the Church inspired cultural achievements in art (e.g., Gothic architecture), poetry (e.g., Dante), philosophy (e.g., Thomas Aquinas), and learning (e.g., the universities of Oxford, Paris, Salamanca, and Bologna). During the Renaissance (c.1400–1550), the Church continued its patronage of the arts, but many areas of Europe (e.g., England, Holland, northern Germany, and Scandinavia) broke with papal authority in the sixteenth century following the Protestant Reformation. In the 1500s and 1600s, missionaries and colonial rulers spread Roman Catholicism into the Americas and Asia.

Although the Roman Catholic Church contributed much to the cultural achievements of the medieval and Renaissance eras, religious minorities, such as the Jews, often suffered persecutions in countries under Roman Catholic control. Theological ideas were enforced by various inquisitions (Church tribunals) that conducted trials for those accused of heresies (false teachings). Technically, the inquisition only had jurisdiction over the baptized, but after the Jews and Muslims were expelled from Iberia in 1492, the Spanish Inquisition would often target Los Conversos, the Jews and Muslims who had accepted baptism rather than leave the country of their birth.

In the 1700s and 1800s, the influence of the Roman Catholic Church over European culture began to fade. The French Revolution (1789–1799) placed the Church in France under virtual state control. In 1870, the Papal States of central Italy were seized from the Church, leaving control only over Vatican City State (according to the Lateran Agreement of 1929).

Deprived of secular power, the Roman Catholic Church in the twentieth century tried to exert moral authority. Pope Pius XI (1857–1939), who was pope from 1922 to his death, issued encyclical letters protesting Italian Fascism (1931), German Nazism (1937), and atheistic Communism (1937). His successor, Pius XII (pope from 1939–1958), led the Church through the difficult years of World War II (1939–1945). His policies during this time—especially with regard to helping the Jews—have been praised by some and criticized by others.

The Second Vatican Council (1962–1965) urged dialogue with other Christians and non-Christians (most notably Jews and Muslims). In his 1994 apostolic letter, Tertio Millennio Adveniente, John Paul II (pope from 1978–2005) called Catholics to a “spirit of repentance” for practices of past centuries that involved “intolerance and even the use of violence in the service of truth.” Pope Benedict XVI, who succeeded John Paul in 2005, has continued this spirit into the early-twenty-first century, while at the same time condemning secularization and moral relativism.

ROMANCE

Social psychologists have defined “romance” in a variety of ways. These include: (1) Tales of idealized romantic love between two lovers; (2) A dreamy, imaginative, cognitive state in which people imagine a perfect love relationship; (3) A feeling of passionate love. In the early 1950s social psychologists focused on romantic love, attempting to discover if couples’ attitudes toward romantic love had an impact on marital happiness and stability. A popular scale at that time was Charles Hobart’s “Romantic Love Scale” (1958). It contained such items as: “When one is in love … one lives almost solely for the other.” Later, in 1973, Zick Rubin developed a more modern scale to measure romantic love versus friendship. Rubin argued that romantic love was made up of three elements: attachment, caring, and intimacy.

DEFINITIONS

By the end of the twentieth century, however, scientists’ attention had shifted to passionate love. Passionate love (sometimes called “obsessive love,” “infatuation,” “lovesickness,” “romantic love,” or “being-in-love”) is a powerful emotional state. It has been defined by Elaine Hatfield and Richard Rapson as “A state of intense longing for union with another. Passionate love is a complex functional whole including appraisals or appreciations, subjective feelings, expressions, patterned physiological processes, action tendencies, and instrumental behaviors. Reciprocated love (union with the other) is associated with fulfillment and ecstasy. Unrequited love (separation) is associated with feelings of emptiness, anxiety, and despair” (1993, p. 5). The Passionate Love Scale is designed to tap into the cognitive, emotional, and behavioral indicants of such longings, as reported by Hatfield and Susan Sprecher in 1986.

GENETIC AND BIOLOGICAL BASES OF LOVE, LUST, AND ATTACHMENT

In the 1990s social psychologists, neuroscientists, and physiologists began to explore the links between romantic and passionate love, sexual desire, and sexual behavior. The first neuroscientists to study romantic and passionate love were Niels Birbaumer and his colleagues in 1993. They concluded that passionate love was “mental chaos.” In 2000 Andreas Bartels and Semir Zeki studied the neural bases of passionate love using fMRI (brain imaging) techniques. They interviewed young men and women from eleven countries who claimed to be “truly, deeply, and madly” in love and who scored high on the Passionate Love Scale. They discovered that passionate love produced increased activity in the brain areas associated with euphoria and reward, and decreased levels of activity in the areas associated with distress and depression. Passionate love and sexual arousal appeared to be tightly linked. Other psychologists who have studied the links between passionate love and sexual desire (using fMRI techniques), such as those reported by Helen Fisher in 2004, have found similar results.

Scientists interested in the chemistry of passionate love, sexual desire, and mating, detailed by C. Sue Carter in 1998 and Donatella Marazziti and Domenico Canale in 2004, have found that a variety of neurochemicals shape romantic love, passionate love, sexual desire, and sexual mating. One theorist, Helen Fisher, argued in 2004 that passionate love, lust, and attachment are associated with slightly different chemical reactions—although generally coming together in a single package. According to Fisher, passionate love is associated with the natural stimulant dopamine (and perhaps norepinephrine and serotonin.) Lust is associated primarily with the hormone testosterone. Attachment (a commitment to another) is produced primarily by the hormones oxytocin and vasopressin.

Psychologists may differ on whether romantic and passionate love are or are not emotions and whether passionate love, sexual desire, and sexual motivation are closely related constructs (both neurobiologically and physiologically) or very different in their natures. Nonetheless, this path-breaking research has the potential to answer age-old questions as to the nature of culture, love, and human sexuality.

CULTURAL DIFFERENCES IN ROMANTIC ATTITUDES, FEELINGS, AND BEHAVIOR

Passionate love is as old as humankind. (The Sumerian love fable of Inanna and Dumuzi was spun by tribal storytellers in 2,000 BCE.) People in all cultures also recognize the power of romantic love. In south Indian Tamil families, for example, a person who falls head-over-heels in love with another is said to be suffering from mayakkam—dizziness, confusion, intoxication, and delusion. The wild hopes and desairs of love are, as Margaret Trawick noted in 1990, thought to “mix you up.”

At one time, however, social commentators contended that the idealization of romantic and passionate love was a peculiarly Western institution. Thus, cultural researchers began to investigate the impact of culture on people’s definitions of love, what they desired in romantic partners, their likelihood of falling in love, the intensity of their passion, and their willingness to acquiesce in arranged marriages versus insisting on marrying for love. When social psychologists explored folk conceptions of love in a variety of cultures—including the People’s Republic of China, Indonesia, Micronesia, Palau, and Turkey—they were surprised to find that men and women in all of these cultures possessed surprisingly similar views.
of romantic love and other “feelings of the heart” (Jankowiak 1995; Shaver, Murdaya, and Fraley 2001). Subsequent research by cultural and evolutionary psychologists discovered that there appear to be cultural universals in what men and women desire in mates (Buss 1994), and according to Hatfield and Rapson’s 1996 work, in their likelihood of being in love, in how intensely they love, and whether or not they would be willing to marry someone they did not love. One impact of globalization (and the ubiquitous MTV, Hollywood and Bollywood movies, chat rooms, and foreign travel) may be to ensure that young people are becoming increasingly similar in their definitions of love and their romantic aspirations and behavior (Hatfield and Rapson 1996; Hatfield, et al. 2007).

**HOW LONG DOES LOVE LAST?**

Like any intense emotion, passionate love does tend to erode with time. Jane Traupmann and Elaine Hatfield in 1981, for example, interviewed a random sample of dating couples, newlyweds, and older women (who had been married an average of thirty-three years) in Madison, Wisconsin. (The longest marriage was fifty-nine years.) The authors assumed that passionate love would decline precipitously with time; they expected companionate love to last far longer. They were wrong. Over time, passionate love did plummet. Couples began loving their partners intensely. Both steady daters and newlyweds expressed “a great deal of passionate love” for their mates. After many years of marriage, however, women reported that they and their husbands now felt only “some” passionate love for one another. And what of the fate of companionate love? The authors found that over time, both passionate and companionate love tended to decline at approximately the same rate. This finding was especially surprising since the authors were only interviewing couples whose marriages had survived for ten, twenty, or fifty years. Couples whose relationships were the most dismal may well have divorced and thus been lost from the sample.

**ROOSEVELT, FRANKLIN D.**

**1882–1945**

Franklin Delano Roosevelt was the thirty-second president of the United States of America. He served as president from March 4, 1933, until his death on April 12, 1945. He was elected president four times, more than any other American president.

Franklin D. Roosevelt was born on January 30, 1882, in Hyde Park, New York. He was the only child of James and Sara (Delano) Roosevelt. A graduate of the Groton School and Harvard University, he also attended the law
school of Columbia University before becoming an attorney in 1907.

Like his father, Franklin D. Roosevelt was a Democrat, but he wanted to follow the career path of his Republican cousin, President Theodore Roosevelt (1901–1909). As a young attorney, Roosevelt became active in the progressive wing of the Democratic Party. In 1910 he was elected to the New York state senate. An admirer and supporter of Democratic president Woodrow Wilson (1913–1921), Roosevelt was appointed assistant secretary of the navy in 1913. Like Wilson, Roosevelt supported an active, leading role for the United States in the League of Nations after World War I.

After the Democratic national convention nominated James Cox for president and Roosevelt for vice president in 1920, the Democratic Party decisively lost the 1920 presidential election. In 1921 Roosevelt was stricken by polio, which permanently paralyzed his legs. After resuming his political activism, Roosevelt became closely allied with Democratic governor Alfred E. Smith of New York; he also relied on his wife, Eleanor Roosevelt, who served as a political operative. After Smith was nominated for president in 1928, Roosevelt, at Smith's request, ran for governor. While Smith lost the 1928 presidential election by a landslide, Roosevelt was narrowly elected governor of New York.

For a Democratic governor, Roosevelt was unusually popular in heavily Republican rural areas of upstate New York. He advocated such policies as state-sponsored rural electrification, property tax relief for farmers, and the state construction of paved farm-to-market roads. He directly communicated to New Yorkers through radio broadcasts, and increased public works and relief spending when the economy worsened after 1929. Reelected in 1930, Roosevelt emerged as the leading candidate for the 1932 Democratic presidential nomination.

Citing his rural-oriented policies as governor, Roosevelt emphasized agricultural and rural economic issues as he gained greater political support in the South and West while the Great Depression worsened. Competing against Smith, Speaker of the House John N. Garner, and several minor candidates, Roosevelt was nominated for president at the 1932 Democratic national convention. He chose Garner as his running mate.

The Great Depression helped Roosevelt to easily defeat Republican president Herbert Hoover in 1932. In his campaign speeches and 1933 inaugural address, Roosevelt promised bold, innovative presidential leadership to combat economic suffering and reform the economy. Roosevelt's domestic policies, collectively known as the New Deal, included public works programs, the Social Security Act of 1935, stricter federal regulation of banks and the stock market, agricultural subsidies, legal powers for labor unions, and a national minimum wage. Roosevelt's landslide reelection in 1936 solidified changes in American voting behavior that caused a Democratic realignment which lasted until 1968.

During his second term (1937–1941), Roosevelt was less successful in realizing his domestic policy agenda. The rejection of his “court-packing bill” in 1937 and Republican gains in the 1938 elections increased opposition in Congress to further New Deal legislation. After the outbreak of World War II in Europe in 1939, Roosevelt concentrated on foreign and defense policies. Before the United States entered World War II following the Japanese attack on Pearl Harbor on December 7, 1941, Roosevelt assisted Great Britain against Nazi Germany through military and economic aid, despite strong isolationist opinion in the United States.

In his treatment of African Americans, Roosevelt generally deferred to the pro-segregation beliefs and policies of white Southern Democrats who dominated Congress and the Democratic Party. He never submitted a civil rights bill to Congress and only reluctantly created a Fair Employment Practices Committee (FEPC) after black civil rights leaders threatened a march on Washington. New Deal programs, especially the Works Progress Administration and Civilian Conservation Corps, were often racially segregated and discriminatory. Roosevelt did not publicly support federal anti-lynching legislation and the American military remained racially segregated during World War II.

Roosevelt was reelected president in 1940 and 1944 by narrower margins. During the period of American participation in World War II (1941–1945), Roosevelt converted the U.S. economy's productive capacity for military and foreign aid purposes and developed military and political alliances with Great Britain and the Soviet Union to defeat Germany and Japan. He also secretly authorized the development of atomic bombs and promoted the creation of the United Nations and the establishment of the concept and practice of international human rights.

RORSCHACH TEST
The Rorschach inkblot test is one of several inkblot-based personality assessment instruments, though it is by far the most well known, commonly used, and frequently researched. Its name is derived from its developer, Hermann Rorschach (1884–1922), a Swiss physician and artist. Rorschach experimented with forty or more inkblots between 1917 and 1920, largely with the goal of understanding the syndrome of schizophrenia (dementia praecox) that had recently been identified and described by his mentor, the Swiss psychiatrist Eugen Bleuler (1857–1939). Contrary to popular perception, these were not simply blots of ink placed on a piece of paper that was folded in half and opened again. Instead, Rorschach used his artistic skills to refine and enhance his final inkblots so that each contained some contours that would suggest objects or images to most people. His interests were in the perceptual operations that contributed to what people saw more than in the content of those perceptions. Ultimately he selected twelve inkblots as most optimal for eliciting and identifying personality characteristics. However, reproducing them was expensive, and Rorschach had to omit two in order to publish the final set of ten in 1921.

Each inkblot appears on a white background. Five are black and gray; two are black, gray, and red; and three are various pastel colors without any black. As the inkblots were prepared for publication, imperfections in the printing process accentuated gradations in saturation that were not obvious before. Rorschach initially was concerned about this but ultimately realized the shading gradations provided another set of perceptual processes that could influence how people perceived the stimuli.

HISTORY
Rorschach died in 1922, less than a year after his work was published. In the late 1920s his test was introduced in the United States, and by the late 1960s five distinct approaches to its use had been developed by the psychologists Samuel Beck, Marguerite Hertz, Bruno Klopfer, Zygmunt Piotrowski, and David Rapaport. Each practitioner had a different approach to administration, scoring, and interpretation of the Rorschach test, which created disorganization in the research literature because there was no single “test” per se. In the late 1960s the American psychologist John Exner (1928–2006) reviewed the similarities and differences between these systems and then in 1974 published the first edition of what he called the Comprehensive System, which synthesized the most logically and empirically defensible elements of the earlier approaches. Fairly quickly the Comprehensive System became the dominant approach to administering, scoring, and interpreting the test in the United States and in other parts of the world. Although not specific to the Comprehensive System, the International Rorschach Society promotes research and clinical practice with the instrument and has twenty-seven member organizations worldwide.

TERMINOLOGY
In the late 1930s the Rorschach was classified as a “projective” test. This term was applied to a range of different kinds of tasks that could be used for personality assessment, such as having people tell imaginative stories that go along with certain pictures or generate pencil drawings of people. The idea was that these tasks required people to project or put forward distinctive aspects of their personality when spontaneously completing an activity without much external guidance. Projective tests were also contrasted with “objective” personality tests, which referred to self-rating questionnaires, where people indicate whether verbal descriptions are characteristic of them, using a fixed set of response options, such as true or false. Although the terms projective and objective are still used, they have misleading connotations and do not do a good job of describing the methods that psychologists can use to assess personality; so increasingly the Rorschach is called a performance task or implicit measure of personality.

ADMINISTRATION, SCORING, AND INTERPRETATION
Regardless of the label, the Rorschach provides a standard set of inkblot stimuli that are used with children, adolescents, and adults in a wide range of settings where questions of personality and problem solving are relevant, including psychiatric, medical, criminal, or legal settings, as well as when assessing normal personality functioning. Using the Comprehensive System's guidelines for standardized administration and scoring, normative reference data are available for children, adolescents, and adults. On average it takes about an hour and a half to administer and score the test. During administration the examiner sits next to the test taker, presents the cards sequentially, saying, “What might this be?” and then records all responses verbatim. On average people give about twenty-two or twenty-three responses, and a minimum of fourteen is
required. To facilitate accurate scoring, the examiner reviews each response a second time and strives to see it through the test taker’s eyes by clarifying the content of what is seen, where it is located in the inkblot, and the perceptual features of the ink that contribute to the response. Each response is then coded on dimensions that include location (e.g., the whole inkblot versus an unusual detail), developmental quality (e.g., vague versus defined object), determinants (e.g., movement, color, shading), form quality (e.g., how typical it is to see an object in a particular location based on an extensive table derived from more than 200,000 responses), content (e.g., human, landscape), organizational synthesis, and a series of special coding categories, many of which indicate disruptions in logic and thought processes. The codes are then summed across all responses to form what is known as the structural summary, which contains about seventy ratios, percentages, and derived scores that are considered important for interpretation. In addition to formal scores, Rorschach interpretation is also based on behaviors expressed during the testing, patterns of scores across responses, unique or consistent themes in the responses, and unique or idiosyncratic perceptions.

Unlike interview-based measures or self-report questionnaires, the Rorschach does not have people describe what they are like but has them show what they are like via the sample of behavior provided in each response. By relying on an actual sample of behavior collected under standardized conditions rather than a self-description, the Rorschach can provide information about personality that may reside outside of a person’s conscious awareness.

ISSUES AND EVIDENCE CONCERNING THE RORSCHACH
The Rorschach has frequently been criticized for lacking reliability and validity. Like most personality inventories, it needs more systematically organized data evaluating the focused validity for each of its scales. In addition, based on emerging findings from around the world, the normative expectations for certain scores probably will need to be adjusted, particularly for children. Nonetheless systematically gathered statistical summaries of the research evidence show that its scores can be reliably coded and they are reasonably stable over time. Globally, across all scores that have been researched, the Rorschach is as valid as other commonly used and widely regarded personality tests. Even the most ardent contemporary critics acknowledge that its scores can validly evaluate disorders of thinking, the accuracy and conventionality of perceptions, psychotic disturbances (such as schizophrenia), dependent personality traits, cognitive complexity, anxiousness, hostility, and the ability to predict who will benefit from psychotherapy. Replicated evidence also shows that the Rorschach can quantify improvement from therapy as validly as other tests, assess the maturity with which other people are perceived, and predict suicidal self-harming behavior.

RORTY, RICHARD
1931–2007
Richard Rorty was at his death a professor of comparative literature and philosophy at Stanford University and one of the most influential and controversial American philosophers of the twentieth century. He crafted a unique version of pragmatism from a blend of Anglo-American analytic philosophy with the Continental tradition, and his impact was felt across a broad range of the humanities and social sciences, including philosophy, literature, political science, and the fine arts.

Rorty was the grandson of Walter Rauschenbusch (1861–1918), a founder of the Social Gospel movement. Though he began his career in academic philosophy, Rorty later emerged as a social critic and political theorist of the first rank, connecting his earlier interest in epistemology with a critique of the foundations of twentieth-

Rorty’s main target, in both epistemology and political philosophy, was the hegemony of the paradigm of “representation” that had been in ascendance since the time of Immanuel Kant (1724–1804). According to Rorty, this tradition privileged a conception of truth that sought to bring the objects “out there” in the world into correspondence with the representations “inside” our heads. This led philosophers into a misguided search for ways of purifying representations (hence the analytic tradition’s emphasis on clarifying linguistic propositions); however, instead of searching for a “final vocabulary” that could somehow bring the world and our representations into complete correspondence, philosophers should have taken up the more mundane tasks issuing from the pragmatism of John Dewey. Since philosophy and language are tools, not objective measuring sticks for determining truth, philosophers should avoid questions of validity, opt for an ironic detachment toward their own pronouncements, and reorient their discipline as therapeutic storytelling rather than rational adjudication.

Rorty’s pragmatism and antifoundationalism were disturbing to both sides of the political spectrum. To the Right he represented the worst of liberal relativism, and to the Left his “liberal ironist” pose seemed to justify political quiescence. From Rorty’s standpoint both sides mistake the issue—we need neither ontological foundations to justify our political stances, nor a fixed vocabulary to inspire us to political action. In any event, Rorty argued, rationality and foundationalist claims to knowledge are never the effective agents in history, since contending ontological positions (say between a Thomist and a Kantian liberal) are not themselves capable of rational resolution—it is in the “sad, sentimental” stories that we tell to one another that ultimate hope for the elimination of cruelty is to be found. This shift in the self-understanding of philosophy is Rorty’s most lasting contribution to the Anglo-American philosophic tradition, and while his idea of philosophy is not universally accepted, it is almost always the one proffered by his opponents as the relevant position to be refuted.

**ROSCAs**

Rotating savings and credit associations (ROSCAs) constitute one of the most commonly found informal financial institutions in the developing world. ROSCAs are known by many different names, such as *susu* in Ghana, *tontines* in francophone Africa, *gamias* in Egypt, *njangis* in Cameroon, *upatu* in Tanzania, *ekub* in Ethiopia, *chilemba* in parts of East Africa, *hagbad* in Somalia, *chit* funds in India, *cheetu* in Sri Lanka, *pasanakus* in Bolivia, *cundina* in Mexico, *kye* in Korea, *arisan* in Indonesia, *pia huey* in Thailand, *kou* in Japan, *hui* in China, and *altin gunu* in Cyprus. The origins of ROSCAs are unclear, but records show that they have existed since premodern times in China, the ninth century in Japan, the seventeenth century in Korea, and the early nineteenth century in many parts of Africa. ROSCAs are particularly prolific in Africa, where they have exceptionally high membership rates (between 50% and 95% of the adult population in many countries). In many rural areas, these associations are the sole saving and credit institution. It has been estimated that the annual sums mobilized in these associations amount to more than 25 percent of national credit for countries of Africa, South Asia, and East Asia. Although ROSCAs are most common in very poor areas of the world, there are places where they exist alongside more formal financial institutions, and where they are sometimes preferred. ROSCAs are also popular among immigrant groups in developed countries.
In these associations, a group of individuals gather for a series of regular meetings, at which each person contributes a predetermined amount into a collective “pot,” which is then given to a single member. This person is subsequently excluded from receiving the pot in future meetings, while still being obliged to contribute to the pot. The meeting process repeats itself until all members have had a turn at receiving the pot. The frequency of the meetings, the amount of the contribution, and the number of members determine the total group savings for each ROSCA cycle. Essentially, members take turns in benefiting from collected savings. Members who receive the pot early in the cycle are in debt to other members until the last contribution, while the last member to receive the pot is a creditor to all other members throughout the ROSCA cycle. As a result, the order of turns is an important component of ROSCAs, and there is substantial variation in its determination. At the start of the scheme, the order of such turns is decided either by a lottery draw, a bidding process, or according to a predetermined pattern.

ROSCAs are usually viewed as a way for individuals with little or no access to formal credit markets to save up for the purchase of indivisible durable goods. There is no interest to be gained by saving in a ROSCA since, over the ROSCA cycle, individual participants contribute the total funds that they, in turn, withdraw from the association. The question, therefore, is why do individuals choose to save through a ROSCA instead of individually accumulating savings? Several rationales for ROSCA formation have been put forth. Timothy Besley and colleagues point to the gains from reduced delay: the participants, on average, expect to enjoy the benefits of savings sooner than if they had saved on their own. Other rationales point to the insurance role of ROSCAs. Stefan Klonner notes that when ROSCA funds are allocated by a bidding process, the participants can use ROSCAs to insure themselves against idiosyncratic risks. Other explanations refer to the savings commitment role of ROSCAs. According to Mary Kay Gugerty, if individuals face self-control problems and are unable to credibly commit themselves to future behavior, then ROSCAs can serve as a collective savings commitment mechanism. A related explanation is that, in many cases, ROSCA participants are predominantly women. In a 2002 article, Siwan Anderson and Jean-Marie Baland pointed out that when men have a greater preference for present consumption, relative to women, then women can use ROSCAs as a forced savings device to hide money from their husbands in order to accumulate savings.

In spite of their organizational simplicity, ROSCAs do suffer from incentive problems. Because of the rotational structure of ROSCAs, the incentive for members who receive the pot earlier in the cycle to defraud on their later contributions is high. A ROSCA cannot function unless all members continue to maintain their obligations throughout the cycle. Since ROSCAs are typically formed by a relatively small group of individuals who live in the same area, it is generally assumed that the threat of social sanctions by the other members of the group are sufficient to deter opportunistic defection. Therefore, social collateral and trust among members seem crucial to the success of these organizations. To this end, as Ngina Chiteji points out in “Promises Kept” (2002), ROSCAs typically organize along ethnic lines or bring together friends and neighbors, for whom existing social capital circumvents inherent problems of enforcement.

ROSENBERG’S SELF-ESTEEM SCALE
Morris Rosenberg’s (1965) Self-Esteem Scale (RSES) is perhaps the most widely used instrument for the assessment of trait self-esteem, defined as relatively stable feelings of overall self-worth. The importance of self-esteem in the prediction of other self-attitudes and behavior in conjunction with the ease of administration and scoring of the RSES make the instrument useful for social scientists in many different settings.
Rosenberg originally designed the RSES as a face-valid, unidimensional measure of self-esteem designed to assess adolescent self-worth. Example items from the RSES include “I feel that I am a person of worth, at least on an equal basis with others” and “At times I think I am no good at all.” Negatively worded items are reverse-scored to create an overall score. The underlying view of self-esteem on which the scale was founded defines self-esteem as a positive or negative attitude about the self. People with high self-esteem respect and consider themselves worthy. Rosenberg noted that high-self-esteem people do not necessarily feel that they are better than others, but they do not consider themselves to be worse than others. People with low self-esteem express “self-rejection, self-dissatisfaction,” and “self-contempt” (Rosenberg 1965, p. 31). According to Rosenberg, low-self-esteem people do not respect themselves and wish that they could evaluate themselves more favorably.

Though Rosenberg fashioned the RSES as a ten-item Guttman scale, researchers most commonly adopt five- or seven-point Likert-style response formats anchored by, for example, 1 = not at all like me to 7 = very much like me. (Blascovich and Tomaka 1991). Internal consistency estimates for the scale typically fall in a range from .77 to .88, indicating acceptable internal reliability. Additionally, test-retest estimates for the RSES range from .85 to .82, revealing that the RSES demonstrates excellent test-retest reliability.

In addition to being reliable, the RSES surfaces as a valid measure of self-worth as well. RSES scores are positively related to an abundance of conceptually related constructs such as confidence and social acceptance, as well as to other self-esteem scales (Blascovich and Tomaka 1991). Moreover, RSES scores are negatively associated with constructs that are typically symptomatic of low self-worth, including anxiety, depression, and feelings of rejection.

Researchers have adapted the RSES for use with different populations (i.e., younger children; Rosenberg and Simmons 1972) and for different purposes. By modifying instructions for the RSES, asking that respondents answer according to how they feel about themselves right now, at the present moment, researchers may assess state self-esteem, an evaluation of self-worth that is more variable than trait self-esteem using the RSES (Kernis, Grannemann, and Barclay 1992).

Although the RSES is a conceptually and psychologically sound measure of unidimensional self-esteem, it does not assess facets of self-worth. Researchers who are interested in assessing domain-specific elements of self-esteem (e.g., appearance self-esteem, school competence, moral self-worth) should include domain-specific measures in addition to or instead of the RSES, depending on their research questions. Additionally, the RSES is transparent, or face valid, making it easy for the respondent to surmise that they are completing a measure of self-esteem. Such obvious face validity might result in artificially inflated self-esteem scores. Researchers who are more interested in people’s automatic or uncontrolled ratings of self-worth should make use of available implicit measures of self-worth.

The Rothschild family, the most influential banking and finance dynasty of modern Europe, began with Mayer Amschel Rothschild (1743–1812) in Frankfurt am Main, Germany, and expanded across Europe under his five sons: Amschel Mayer Rothschild (1773–1855) in Frankfurt; Salomon Rothschild (1774–1855) in Vienna, Austria; Nathan Mayer Rothschild (1777–1836) in London, England; Karl Rothschild (1788–1855) in Naples, Italy; and James Rothschild (1792–1868) in Paris, France. Throughout its history, the family has used its unparalleled, networked financial and political assets to support large-scale government borrowing, industrial development, health, education, art collecting, scientific discovery, and Jewish rights.

After moving from Frankfurt to Manchester in 1799, Nathan used the expanding British cotton industry to accelerate the process of wealth accumulation started by his father. He consolidated large quantities of fabric for export from many of the smaller British cloth manufacturers, and supplied these producers with dyes and other raw materials. Using the profits that he earned, Nathan moved to London and refocused on the bullion market. Buoyed by his father’s and brothers’ continental connections, Nathan smuggled gold through Napoléon Bonaparte’s continental blockade, funded the Duke of Wellington’s Peninsular and Waterloo campaigns, propped up the Bank of England during the liquidity crisis of 1834, and created a new European state bond market based on easily tradable notes. Benefiting from carefully cultivated friendships with royal and political leaders, Nathan’s brothers worked with the governments of France, Austria, and Belgium to finance the reconstruction of Europe, devastated by two decades of war. Beginning in the 1840s they established much of the continental railway network. Through their railways, as well as their development of mining and oil exploration, the Rothschilds powered nineteenth-century industrial growth from Spain to Russia. The Rothschilds also played an instrumental role in late nineteenth-century British imperial expansion, financing the Suez Canal Company and the South African diamond trade.

Like its banking concerns, the family’s philanthropic activities have been global, including the building and support of hospitals, schools, and art collections. As a result of intense family pursuit of the natural sciences, more than 150 insect species, 81 animal species, and 14 plant species bear the Rothschild name. Beginning with the Rothschild’s early years in the Jewish ghetto, however, anti-Semites viciously attacked the family for its adherence to Judaism, its high-profile wealth, and its Zionist support. Throughout, the Rothschilds remained proud of their faith, and actively supported Jewish personal and legal rights around the world. Nathan’s son, Lionel Nathan Rothschild (1808–1879) successfully fought to become Britain’s first Jewish member of Parliament in 1847. During World War II (1939–1945), the family suffered substantial loss and hardship in Nazi-occupied Europe. After the war, the Rothschilds expanded into North America, most prominently through the Brinco resource and hydroelectric development scheme in Newfoundland. In the 1980s the French government nationalized the original Paris branch, while the British government depended on the London branch to privatize several major public corporations. Signaling their new emphasis on corporate finance, in 2004 the Rothschilds withdrew from the bullion market that had been critical to their early success.

ROTTEN KID THEOREM
SEE Bequests.

ROTTER, JULIAN
SEE Locus of Control.

ROTTER’S INTERNAL-EXTERNAL LOCUS OF CONTROL SCALE
In an effort to explain how personal characteristics interact with the environment to predict behavior, the psychologist Julian Rotter (b. 1916) proposed a social learning theory in 1954. Although Rotter emphasized both personal and environmental factors in behavioral prediction, much of the research generated by his theory focused on the role of people’s expectancies or their subjective estimates of how likely it is that a given behavior will lead to a desired outcome.

According to Rotter, there are two types of expectancies. Specific expectancies apply to single situations, such as whether a student expects to do well on an exam. Over
time people learn to apply their expectancies to a variety of related experiences, resulting in generalized expectancies. A generalized expectancy might refer to how well a student expects to do on exams in all of his or her courses. Rotter proposed that one of the most important generalized expectancies is a person's locus of control (LOC).

LOC refers to the perceived location of reinforcement sources for a person—that is, who or what is responsible to the things that happen to a person. As such, it is similar to other control-related constructs, such as attributions, learned helplessness, and self-efficacy. Those with an internal LOC expect the important things in their lives to occur because of their own effort, skills, or abilities. People with an external LOC expect these things to occur because of outside forces (such as luck, fate, chance, or powerful others).

In 1966 Rotter published the Internal-External Locus of Control Scale. Respondents were asked to choose between pairs of internal and external items relating to everyday situations. For example, on one item respondents must choose whether people's misfortunes are due to their own mistakes (internal) or to bad luck (external). Since its formulation, LOC has been one of the most frequently researched personality variables in the social sciences. Scores on the LOC Scale have been correlated with scores on nearly every social and personality characteristic imaginable. Among the areas that most commonly have used the LOC Scale are personality and social, educational, political, clinical, and health psychology. For example, research shows that whereas high externality scores are associated with high depression scores, internality is associated with more positive adjustment to a physical disability. In addition discrimination based on race or sex has been associated with differences in LOC. Researchers have shown that such group-level internality-externality differences have implications for mental and physical health outcomes.

Researchers have focused a great deal of attention on the psychometric properties and factor structure of the LOC Scale. In Rotter's original conception, LOC was a unitary construct along the internality-externality dimension. However, researchers soon began uncovering several other dimensions related to LOC. Initial analyses revealed a personal control factor and a system (or political) control factor. Other researchers proposed independent dimensions of internality, chance, and powerful others. Based in part on dissatisfaction with the properties of the original scale, researchers have developed new content-specific, multidimensional LOC measures. One of the most popular is a measure of health LOC (Wallston, Wallston, and DeVellis 1978). Although interest in Rotter's original LOC scale has waned, the development of new measures ensures that LOC will continue to be a topic of interest to social scientists for years to come.

Thomas M. Brinthaupt

ROUSSEAU, JEAN-JACQUES

1712–1778

Born in Geneva, Switzerland, Jean-Jacques Rousseau spent much of his life in and around Paris acting as the gadfly of the philosophes, leaders of the French Enlightenment. He championed equality and popular sovereignty on the eve of the French Revolution, encouraged the birth of nationalism, historicism, and romanticism, and provided prescient critiques of the “bourgeois,” the quintessential figure of the democratic age he helped launch.

In On the Social Contract (1762), Rousseau denied the existence of any natural hierarchy or divine right that could legitimize political inequality, arguing that natural inequalities between human beings were politically irrelevant. The social contract substituted “a moral and legitimate equality for whatever inequality nature may have placed between men, and ... while they may be unequal in force or genius, they all become equal by convention and right” (On the Social Contract, I.ix). While he believed every legitimate government was republican, he understood by this only that the executive power should be beholden to the sovereign people (II.vi). His preferred regime was an aristocratic government, or executive, responsible to the people (III.vi). Ironically, while he was one of the first political thinkers to champion popular sovereignty, he maintained that a democratic government was suited only to a people of gods (III.iv).

Central to his political thought was the general will: the will of the political community as a whole, manifest in laws to which all citizens had consented and by which all
were bound (II.iv). Rousseau held that “what generalizes the will is not so much the number of votes, as it is the common interest which unites them” (II.iv), and he wrote extensively, in Considerations on the Government of Poland (1772) and the Letter to M. d’Alembert on the Theatre (1758), on the need to encourage community spirit through civic education and the promotion of virtue. His emphasis on the particular character of political communities inspired the rise of nationalism, influencing the German philosophers Johann Gottfried Herder (1744–1803) and Johann Gottlieb Fichte (1762–1814).

The argument of The Discourse on the Origins of Inequality (1754) helped give birth to historicism: the idea that human ideas and actions are better explained by history rather than by nature or divine will. History, not nature, nor God, was responsible for the great paradox that: “Man is born free, and everywhere he is in chains” (On the Social Contract, I.i). Free, contented, but asocial by nature, humans could hope only to legitimate rather than remove the chains brought by political life.

Rousseau’s autobiographical work, especially The Confessions (1782), his praise of nature, particularly in The Reveries of the Solitary Walker (1782), and his argument in the Discourse on the Sciences and Arts (1751) that the popularization of science diverted people from the practice of moral duties, all contributed to the romantic movement.

Rousseau also offered one of the first critiques of the “bourgeois.” Alienated from nature, without being committed to political life, the bourgeois were torn between private interests and public duties. Materialistic and inauthentic, they were enslaved by the opinions of others and strangers to themselves.

ROYAL COMMISSIONS

In Britain and in some of its former colonies such as Australia, Canada, and New Zealand, Royal Commissions of Inquiry have been an ad hoc, flexible, adaptive, and adaptable mode of inquiry established by centralized authority to investigate nominated issues. These topics are specified within a Royal Commission’s Terms of Reference and approved under the royal prerogative in its Letters Patent. The first recorded Royal Commission in England is better known as the Domesday Book, ordered by the Norman conqueror William I and compiled between 1080 and 1086. It was an information-gathering exercise for taxation purposes that also sought to cement the authority of a foreign king over his newly conquered population. That Royal Commissions have survived for almost a thousand years since the Domesday Book inquiry is testimony to their flexibility. Royal Commissions, like many other mechanisms of official inquiry, have continued to perform one or both of two broad functions for the state: (1) a pragmatic and/or legal function to investigate an issue for a government, collect information, submit a report, and make recommendations; and (2) a broader political, or ideological, function as a technique of governance, in particular a capability for crisis management of an issue or a range of issues.

In carrying out either, or both, of these broad functions as an information gatherer or a mechanism that provides breathing space for governments, Royal Commissions can be investigatory, inquisitorial, or a combination of both. Their capacity for coercive powers of investigation varies between jurisdictions, but in Australia, for example, they include the ability to compel the attendance of witnesses and/or the production of documents, and to examine witnesses under oath or affirmation. Australia, like the United States, is a federal jurisdiction, so the statutes underpinning the legality of a Royal Commission, can operate at a federal level, such as the Royal Commissions Act 1902, or at a state level, such as the Commission of Inquiry Statute 1854 in the state of Victoria. In Britain, Royal Commissions are established under the Tribunal of Inquiry Act 1921. There is little doubt that political considerations can be a major influence upon the establishment of Royal Commissions. Once governments have decided to establish a Royal Commission they are faced with a range of decisions regarding the form, direction, and timescale of the inquiry. They are not merely the decisions of a minister, but also reflect the opinion of a permanent civil bureaucracy. Generally, civil bureaucrats provide government ministers with advice and draft the actual terms of reference for a Royal Commission. They also provide the secretary and often a short list of appropriate potential commissioners. There has been a traditional tendency in
most jurisdictions that operate Royal Commissions to appoint judges and lawyers to head such inquiries, as they are assumed to bring impartiality and independence, plus appropriate skill sets to manage large amounts of information and direct the cross-examination of witnesses.

It is difficult to evaluate just how effective Royal Commissions are. They do have a somewhat dark side historically, in that some Royal Commissions have been used as political mechanisms by various monarchs and governments. However, many Royal Commissions have brought positive social, political, and economic benefits as they gathered information on issues, established fact, helped resolve disputes, and stimulated worthwhile reform. History demonstrates that Royal Commissions have been too diverse and adaptive to be tied down to a single explanatory model, and their intrinsic adaptability and flexibility are likely to ensure their survival into the foreseeable future.

RULE OF LAW
The rule of law characterizes polities where coercive state action is efficiently exercised in accordance with generally applicable authoritative rules, adopted according to an agreed-upon and public procedure, and not contrary to certain fundamental natural rights. The concept is intrinsic to the Western idea of a legitimate legal system.

The most famous exposition of the rule of law was made by British constitutionalist Albert Venn Dicey (1835–1922) in his Introduction to the Study of the Law of the Constitution in 1895. Dicey saw the rule of law as embodying three “kindred conceptions”: (1) that no one is punishable or can be made to suffer in body or goods except for a distinct breach of law established in the ordinary legal manner before the ordinary courts of the land; (2) that the same general law applies to the rulers as to the ruled; and (3) that individual rights are enforced, not simply proclaimed (Dicey [1895] 1982, pp. 107–122). John Adams (1735–1826), in Article XXX of the 1780 Massachusetts Constitution, added a fourth, quintessentially American contribution to the rule of law: separation of powers. “The legislative department shall never exercise the executive and judicial powers, or either of them: the executive shall never exercise the legislative and judicial powers, or either of them: the judicial shall never exercise the legislative and executive powers, or either of them: to the end it may be a government of laws and not of men.”

Good organization has been an implicit part of the rule of law since King John (c. 1167–1216) of England was forced to approve the Magna Carta in 1215: “To no one will We sell, to no one will We deny or delay, right or justice” (Magna Carta, c.1. 40).

Legalism (respect by the state for, and enforcement of, its laws) is also an important part of the rule of law. This legalism arguably characterized Soviet and, to a large extent, even Nazi rule, however. Legalism is necessary but not sufficient: fundamental individual rights, arguably inherent in Dicey’s third kindred conception, are necessary too.

In sum, the rule of law seems to comprise four requirements (five if separation of powers is added):

1. Government is bound by the law.
2. The law is discernible by citizens.
3. Application of the law is well-organized.
4. Ordered liberty is largely maintained; that is, citizens are reasonably secure in their persons and property.

This rule of law can, within these constraints, exist in different legal systems. Republics and parliamentary democracies, civil and common law systems, are compatible with it. Differing tax rates and differing notions of fundamental rights are also compatible with the rule of law. On the other hand, rule-of-law procedural rights, such as the presumption of innocence (citizens are to be treated as innocent until they have been proven guilty), nonretroactivity (no one can be held accountable for violating a law before it was in effect), and habeas corpus (detained persons have the right to have their custody justified both to them and to an independent judicial authority), are intrinsic to the rule of law. Procedure is
related to substance here: only if a legal system were substantially and severely unjust might, for example, retroactivity be authorized to eliminate the injustice.

The concept is elusive and fluid, but utterly meaningful. British philosopher Michael Oakeshott (1901–1990) put it best in his essay “The Rule of Law”: “The rule of law bakes no bread, it is unable to distribute loaves or fishes (it has none), and it cannot protect itself against external assault, but it remains the most civilized and least burdensome conception of a state yet to be devised” (1983, p. 164).

RULES VERSUS DISCRETION

The debate of rules versus discretion in economic policy has its origin in the writings of Henry Simons at the University of Chicago. A policy rule can be specific as fixing the quantity of currency and demand deposits, or general as when the Federal Reserve announces to the public the course of action it will take for various states of the economy, putting its reputation behind it. Although rules can be set up in an equation form, such as the Taylor Rule, they require variables such as the natural level of output and expected prices that are only approximate. A rule can be active, as when it requires increasing the money supply when the economy is on a downswing, or passive when the money supply is increased by a fixed percent annually. By definition rules are normative, but some rules are descriptive, meaning that they predict values close to what the authorities actually allow. The danger with rules is the tendency to substitute administrative authority for rules, which tends to impair competition and expand government activities. In 1990, President George H. W. Bush replaced the term “policy rule” with “systematic policy” or “policy system” in his message to Congress.

Discretion requires delegating responsibilities to economic institutions such as the Federal Reserve to decide macroeconomic goals and policies as they see appropriate. According to Kenneth Arrow, the world of uncertainty necessitates discretionary policies. A decision improves with time and experience, which requires information that is available only sequentially. A decision maker such as the Federal Reserve analyzes the problem at hand, and decides on the best policy action to take. Discretionary policy may be inconsistent when it does not change the initial conditions that create a disturbance, or shortsighted when a policy requires lags to materialize.

Economists are divided over whether rules or discretion is the best policy for managing the economy. In the short run, monetary and fiscal policies can affect income, but in the long run, they do not have permanent effects on real income. The monetarist's preferred habitat is the long run, managing the economy through simple rules of the money supply. Milton Friedman believed that the Federal Reserve did not use its discretion to act when the money supply declined by a third during the 1929–1933 period, turning a garden-variety recession into the Great Depression. However, Keynesians find that output, unemployment, and prices can be stabilized in the short run by autonomous expenditures, including those by the government. Franco Modigliani believed that the deep business cycle in 1974 was a consequence of following monetary rules that did not allow the money supply to adapt adequately in both the up and down swings of the cycle.

The debate over rules versus discretion is not settled empirically. If a rule is placed on the money supply, the monetarists look for a causal link between money and prices. The definition of money and a stable velocity-of-circulation function are necessary for empirical investigation. A currency plus demand-deposit definition is not sufficient for rules to work because people hoard and dishoard money, many “near money” substitutes may exist, or wages and prices may be rigid. If wage and price rigidities are only slight, then a rule might work, but it would require the absence of substitutes such as equity or bonds; it would also require that loans be held for long periods so that repayment on principal is not required.
For Simon, such a systemic policy appears paradoxical, as it would require an intelligent monetary system on the one hand, and credibility of rules on the other. Friedman, a student of Simon, moved the research forward by articulating two rules on the money supply, the k-percent rule, and a Friedman rule, which he later referred to as the “5 percent and the 2 percent rules,” respectively (Friedman 1969, p. 48). In the 5 percent rule, “the aggregate quantity of money is automatically determined by the requirements of domestic stability” (Friedman 1948, p. 252). To cover the international scene as well, Friedman complemented the 5 percent rule with a flexible exchange rate. The 5 percent rule, however, runs up against rigidities and lag effects in the economy, which are short run in nature. The long-run 2 percent rule requires nominal interest rates to equal the opportunity cost of producing money for the interest rate to be approximately zero.

The test for a stable velocity-of-money function was indirect. Because the velocity function was variable in the short run, Friedman turned to more general evidences, including the use of his permanent-income concept for further empirical analysis. Regression analysis on demand for the money function between money and prices was significant but did not assign causal agency to money alone. The issue became more complicated in the short run when interest rates, a mostly Keynesian variable, turned up significant. Abraham Hirsch and Neil De Marchi examined ruling out common elements in a variety of results tested in order to help identify money as the cause of price changes. Such method of difference testing, coined by John Stuart Mill, cannot be exhaustive.

As more sophisticated models evolved, policy rules became hard to eliminate, and according to Finn Kydland and Edward Prescott, they could improve social optimum. A change in administration leads people to change their expectations and set into motion a series of iterative changes that may or may not converge to an equilibrium given the current state of the economy. Some policy rules are suboptimal in the sense that their feedback mechanisms depend on initial conditions, and to continue initial policy in subsequent periods is not optimal.

The discretion to print more money can create unexpected inflation. Robert J. Barro and David Gordon argued that people would adjust their expectation of inflation to eliminate surprise inflation, creating a potential for higher money supply and inflations in equilibrium. If policy rules are implemented, such expectations-driven inflation would not occur, but policy makers would have an incentive to break the rule—cheating—because higher inflation means less unemployment and more growth, according to the Phillips curve. These gaming situations between policy makers and the public can be avoided if policy makers are concerned about their “reputation” or “credibility.” The incentive to be credible is based on a substitution of short-term benefits for higher level benefits from lower inflation in the long run.

Other research focuses on ways to pinpoint a rule and extend it into more research areas. William Poole lauds a Taylor Rule that can be refined, much like a scientist would refine a constant. He likens a rule to the choice of using rules to fly a plane rather than letting the pilot have his or her way of navigating. Taylor extended his policy rule to price and nominal income rules for the open economy under fixed versus flexible exchange rates. He found that the nominal income rule outperformed the price rule. Considering the effect of exchange rates on aggregate supply, Richard Froyen and Alfred Guender show that the nominal income rule is weak. V. V. Chari and Patrick Kehoe found that as of 2002, approximately twenty-two countries use some form of rule-based policy.

RUMORS

Rumor is unconfirmed information circulating among persons endeavoring to make sense of a situation that is ambiguous or one that is potentially threatening. Like news, rumor is of current or topical interest and is generally considered important or significant; unlike news, it is never verified. Participants may or may not be aware of the rumor’s unstable foundation—they may regard it as fact. Nevertheless, doubtful or deficient supporting evidence is rumor’s central defining feature.

FUNCTIONS AND CONTEXTS

Rumors are typically discussed by people trying to make sense of an ambiguous situation or to manage a physical or psychological threat. An example of a sense-making rumor in a school district setting is: “I heard that the real reason the school superintendent was forced to step down was because of certain off-color remarks she made to employees.” Faced with a murky state of affairs in which the meaning of current events is not clear or the likelihood of future events is uncertain, people fill the information void with speculation, discussion, and evaluation. Such collective sense-making attempts employ rumors as working hypotheses. Rumors also help people to manage physical threat, sometimes by warning them of how to avoid a potential future negative event, for example: “Get out of town now! A tsunami is headed this way!” More often, rumors simply afford a psychological sense of control over the threat by helping people understand and interpret negative events, for example: “I heard that the department is being downsized despite strong profits this quarter because the new CEO wants short term stock gains (so he can sell his own shares for a windfall before moving on) and doesn’t care about long term effects on the company.”

Rumors may also help manage threats to one’s psychological sense of self, often by derogating groups with whom one is not associated; one way of building oneself up is to put others down. An example of one such (false) rumor is: “The Israeli government is behind the events of September 11, 2001: 4,000 Jews were told by the Israeli Secret Service not to show up for work at the World Trade Center that day.” Rumors may of course perform more than one of these functions, as when people discuss rumors to make sense of a threatening situation in a way that derogates another social group. Thus rumor is what people collectively do when they find themselves in an unclear or potentially threatening set of circumstances.

COMPARISON WITH GOSSIP

Rumor is often confused with gossip, but there are important differences. Whereas rumor is unverified information circulated to make sense and manage threat, gossip is evaluative social chat about individuals that may or may not be verified. Gossip is idle chit-chat about an individual—typically not present—whose content is often slanderous and personal. Though an important social phenomenon, gossip talk is perceived as less serious, significant, and purposeful than rumor talk. Gossip is part of a relaxed session of shooting the breeze. A classic example is: “Did you hear? Bill and Jennifer are an item!” It matters not whether the statement is firsthand observation or remote speculation; it qualifies as gossip in either case. Thus gossip may or may not be verified, but rumor is never verified. Gossiping to another person tends to strengthen the social bonds between the gossiper and the listener—the listener feels like a privileged insider—and gossip at the same time weakens the social standing of the gossip target. Gossip can be therefore a type of aggression that often attacks another person’s relationships and excludes the target from the group. Gossip also serves to convey and reinforce social norms of the group by way of comparison. The statement “Did you hear what Sally did at the Christmas party?” may laud or shame Sally’s behavior—depending on the speaker’s tone of voice. Though gossip is often negative, it performs a positive function in that it allows people to gain information about a larger group—albeit in a secondhand fashion—that would not be possible if they were limited to firsthand interactions. “Johnny steals from people” is useful social information if a person is deciding who to invite to a party. Finally, gossip is often entertaining—a mutual mood enhancer that again strengthens bonds between participants.

Michael Szenberg
COMPARISON WITH URBAN
LEGEND
Urban (also called modern or contemporary) legends also differ from rumors in their characteristic content, function, and context. Whereas rumors are unverified claims circulated in a collective sense-making effort, urban legends are entertaining stories containing themes related to the modern world that are often funny or horrible and usually teach a moral lesson. The urban legend first of all tells a story—it is a narrative with a background, plot, climax, and conclusion; a rumor is typically not that complex and is often a one-liner. Urban legends are often entertaining and tell a morality tale; rumors are not set forth primarily to entertain or propagate norms. For example, when a teenager couple was unable to start their car after necking on a secluded country road, the boyfriend went for help, only to be found dead the next morning hanging upside down above the car, his fingernails scraping against the hood in a macabre fashion. Moral of the story: Don't park! Urban legends are stories about modern themes, such as automobiles, Coca-Cola®, and computers. In addition an urban legend is characteristically migratory, that is, its details vary from time to time and from place to place. However, urban legends may instantiate as specific rumors. For example, stories about the thief who hid underneath a parked car at a shopping mall and—upon the return of the shopper—slashed her exposed ankles with a razor and stole her bags and her car constitute a well-known urban legend. However, “I heard that a woman was slashed on the ankles by a robber at Jonestown Mall last Saturday night” would constitute a rumor.

Of course these forms of informal human discourse sometimes do not fall neatly into one or the other category. Rumors sometimes possess a narrative structure and entertain. Passing a rumor may also endear the speaker to the listener, convey moral norms, and contain slander about an absent third party. Nebulous and intermediate forms do exist. On the whole, however, rumors, gossip, and urban legends tend to possess the divergent qualities discussed above: Rumors are unverified claims circulating during group sense making and threat management, gossip is evaluative social chat, and urban legends are entertaining narratives.

TYPES OF RUMORS
Rumors have been categorized according to a number of different typologies. They have been grouped by subject matter, for example, racial, disaster, organizational, political, and product rumors. They have been classified according to the rumor public—the group through which the rumor circulates. For example, internal organizational rumors circulate among employees, vendors, and stockholders associated with an organization; external rumors circulate among the general public outside of an organization. They have been classified by object of collective concern of the rumor public. For example, pecking order rumors are about changes in management structure and how this might affect job duties and compensation. Stock market rumors circulate among shareholders who want to profit from changing stock values. Organizational change rumors often concern whether or not the change will be effective and how it will affect working conditions. Perhaps the most common rumor typology is by motivational tension. Dread or fear rumors are about potential negative events (e.g., “I heard that twenty-five staff members will be laid off”), whereas wish rumors are about desired positive events (e.g., “We are getting a Christmas bonus this year!”). Wedge-driving rumors derogate other groups (e.g., during World War II “the Catholics are evading the draft” enjoyed audience among non-Catholics).

EFFECTS OF RUMOR
Rumors cause or materially contribute to a variety of outcomes. Rumors can have attitudinal effects, such as sully ing a company’s reputation (e.g., “Corporation x contributes to the Church of Satan”) or fostering hatred toward another group (e.g., “Ethnic Group y greeted the World Trade Center bombing with celebration”). Rumors also result in behavioral outcomes, such as reducing sales (e.g., “Soft Drink Company z is owned by the Ku Klux Klan and puts a substance in their soda that makes black men sterile”), fomenting a riot (e.g., rumors that police caused the death by impalement of a Native Australian by chasing him on his bicycle led to extensive rioting in Sydney), or fostering noninvolvement in disaster relief (e.g., rumors that water flooding New Orleans—after Hurricane Katrina—was toxic kept many workers from participating in rescue operations). Negative rumors in particular affect a variety of organizational attitudes and behaviors, including job satisfaction, organizational commitment, morale, trust in management, productivity, and intention to leave. For example, in a division of one large company, hearing negative rumors about management month after month led to significant increase in negative work attitudes and intentions. Rumors during organizational change are also associated with greater employee stress. Rumors also affect stock market trading behaviors. Experimental investigations have suggested that rumors draw investors away from profitable buy low, sell high trading strategies. And field studies confirm that the stock market is strongly responsive to rumors. Surprisingly, rumors can have these effects even though they are not believed. For example, disaster rumors circulating in 1934 after a catastrophic earthquake in India were not believed but were still acted upon.
FACTORS IN RUMOR TRANSMISSION

Several variables have been associated with rumor transmission. Uncertainty about a situation—being filled with questions about what current events mean or what future events will occur—leads to speculation and rumor as people try to understand their environment and predict what will happen in the future. Anxiety—an emotional state of dread concerning a potential negative event—promotes rumor discussion as people talk with one another in an attempt to thwart the dreaded negative event or to feel better about it by regaining a psychological sense of control. In addition people tend to discuss important rumors—rumors that pertain to an outcome that is personally relevant to them. People also pass along rumors they believe more than those they disbelieve. Poorly managed manufacturing plant layoff situations where employees are given minimal information provide an example of all these factors in action. Employees in such situations are naturally filled with uncertainty; the prospect of losing one’s job is anxiety provoking; the topic is an important one; employees often have no control over such decisions; and if trust is low, negative rumors about management are quite believable. Rumors in such situations are rife. Rumor transmission may also be viewed through a motivational lens. People often spread and discuss rumors in order to find facts, that is, to ascertain a true state of affairs and to make sense of ambiguity. Telling rumors is fundamentally a social act, however, and people may also spread them to enhance their relationships. “I heard that your university is excellent,” for example, will tend to improve the teller-listener relationship. Finally, rumors may be told to boost one's self esteem. Self-enhancing rumors typically do this by putting other groups down in order to build up one's own group in contrast—and by association, oneself.

FACTORS AFFECTING RUMOR BELIEF

At least four factors have been associated with belief in rumor. Not surprisingly, rumors in agreement with one’s currently held attitudes are more likely to be believed than those that disagree. For example, rumors of government waste and special privilege during the rationing programs necessitated by World War II were more apt to be believed by those opposed to the Roosevelt administration than those in favor of it. Rumors that proceed from a credible source are more likely to be believed than those spread by a non-credible one. In a series of laboratory experiments, rumors about a murder were more likely to be believed when they were heard from someone close to the detective investigating the case than from an elderly busybody with no apparent connection to the case. Repeated hearing of a rumor is also associated with belief. After initial skepticism, a Wall Street stockbroker began to place greater credence in a false rumor that the Clinton White House was covering up the true nature of top aide Vince Foster’s death; this occurred solely because he had heard it several times. Finally, hearing a rumor denial reduces belief in the rumor. In one experiment, denying rumors that admittance to a sought-after academic psychology program would be tightened reduced belief in that rumor.

RUMOR ACCURACY

Sometimes collectives are good at ferreting out the facts—and sometimes they are bad at it. For example, rumors circulating in established organizational grapevines tend to be accurate, but rumors following natural disasters tend to be fallacious. Several types of mechanisms have been identified in rumor accuracy. Cognitive mechanisms, such as the narrowing of attention, memory limits, and perceptual biases, tend to reduce accuracy during transmission. Student who serially transmitted rumors—passed them along a chain—tended to pass along parts of a rumor that were more consistent than inconsistent with stereotypes because stereotype consistent information is easier to process. Motivational mechanisms, including fact-finding, relationship-enhancement, and self-enhancement motives, also play a part. Rumors spread by people intent on fact finding tend to become more accurate than those motivated by either relationship- or self-enhancement. Situational features, such as the ability to check on the veracity of the rumor, tend to increase rumor accuracy. Soldiers in one World War II field study could ask superior officers if rumors they heard were false; rumors circulating among this group were highly accurate. Group mechanisms, such as conformity, culture, and epistemic norms, also affect accuracy. In one observational study of rumors among prison inmates, rumors about who was snitching circulated until a consensus was reached, then conformity to that rumor was demanded. Rumors also tend to agree with the cultural axioms and ideas of the rumor public. Finally, social network mechanisms affect transmission and include interaction among participants and transmission patterns. Rumors transmitted serially with interaction between each teller-listener pair in one laboratory study were more accurate than those where discussion was not permitted.

MANAGING RUMOR

Not all rumors are harmful, but those that are remain an object of interest to those interested in preventing or ameliorating such harm. Rumors can be successfully prevented and managed by reducing uncertainty and anxiety, reducing belief in rumor, or reducing dissemination. A sample of experienced public relations officers recommended rumor prevention strategies that reduce uncer-
tainty and enhance formal communications. Strategies rated most highly in effectiveness include stating the values and procedures that will guide organizational change, explaining how decisions will be made, and—if true—confirming the rumor. Increasing trust was also rated highly; in independent research, distrust of management was strongly related to negative rumor transmission in a department facing radical downsizing. Rumor rebuttal—denying the truth of the rumor—is overall an effective rumor management strategy (given that the rumor is indeed false). It is also a more effective strategy than one commonly advocated by some business commentators: no comment. Presenting a no-comment statement to experimental participants who had heard negative rumors about a food manufacturer raised their level of uncertainty and suspicion as much as simply hearing the rumor alone. Some variables moderate the effectiveness of rebuttals; rebuttals proceeding from a source perceived to be appropriate (i.e., knowledgeable regarding the rumor) and honest were most effective in reducing belief in a rumor. Indeed trusted third-party sources of rebuttal are effective. In addition effective rebuttals assist the recipient in attaining a sense of control; for example, rebuttals can include specific actions the hearer can take in order to minimize potential harm from a dreaded negative event. Finally, effective rebuttals can include a rebuttal context that addresses why the rebuttal is being issued; for example, “A competitor is spreading false and malicious rumors, and that is why we are rebutting them today.”

RUSSIAN ECONOMICS
The development of economic theory in Russia is most conveniently divided into a number of separate periods that are bounded by various dramatic changes in the social and political life of the country. Before the emancipation of the serfs in 1861, Russian economics was in many ways imitative of currents of economic theory that were prevalent in the West. Peter the Great (1672–1725) has been interpreted as drawing inspiration from mercantilism for his program of industrial development focused on Saint Petersburg, while physiocracy found expression in the Russian context through the works of Dmitri A. Golitsyn (1734–1803). Classical economics was a major presence across the nineteenth century through the influence of Adam Smith (1723–1790) and his pupils, the first Russian translation of The Wealth of Nations (1776) being published in four parts between 1802 and 1806. Heinrich F. Storch (1766–1835) was a noteworthy commentator on Smith’s work within Russian borders. Other important Russian economists from the first half of the nineteenth century were Nikolai S. Mordvinov (1754–1845), a supporter of protectionism, and Nikolai I. Turgenev (1789–1871), an advocate of free trade.

After 1861 the originality of Russian economics began to increase dramatically, although Western currents like historical political economy still had a significant influence through Russian representatives such as Ivan K. Babst (1823–1881). Marxists such as Georgii V. Plekhanov (1856–1918) articulated the position that, already in the 1880s, capitalism was successfully developing in Russia, against the populist view that there could never be enough domestic demand for a “mature” form of capitalism to become firmly established. A key issue for Russian economists of this period was the resilience of the peasant commune (or village community), an indigenous institution that practiced the periodic redistribution of arable land. Some argued that such primitive forms of communism were already obsolete, while others maintained that they could be the springboard for future socialist success. Vladimir I. Lenin (1870–1924) argued in favor of the former position, and documented in detail how capitalist industry was rapidly developing within Russian borders. Ironically, given Lenin’s assumption of state power in 1917, Karl Marx (1818–1883) came to believe late in his life that the Russian peasant commune could provide a basis for bypassing much of the capitalist phase of historical development, if certain conditions were met. Marx’s economic ideas were disseminated in Russia by sympathetic advocates such as Nikolai I. Sieber (1844–1888).

THE GOLDEN ERA
The most inventive and influential “golden era” of Russian economics can be given as occurring between 1890 and 1929, this period being subdivided into prerevolutionary and postrevolutionary segments. In the prerevolutionary golden era, the most significant names in Russian economics were Mikhail I. Tugan-Baranovsky (1865–1919), Vladimir K. Dmitriev (1868–1913), Petr B. Struve (1870–1944), Aleksandr I. Chuprov (1842–1908), Sergei N. Bulgakov (1871–1944), and Dmitrii I. Mendeleev (1834–1907). In the postrevolutionary golden era, the most significant names in Soviet economics were Nikolai D. Kondratiev (1892–1938), Eugen E. Slutsky (1880–1948), Alexander V. Chayanov (1888–1939), Evgeny A. Preobrazhensky (1886–1937), Leonid N. Yurovsky (1884–1938), Vladimir G. Groman (1874–1937), Vladimir A. Bazarov (1874–1939), and Grigorii A. Feldman (1884–1958). For reasons of space, the work of only the main aspects of some of the most significant of these economists can be discussed here.

Tugan-Baranovsky’s most important contribution to economic theory was Industrial Crises in Contemporary England (1894). This book pioneered the empirical description of business cycles by documenting the interrelated movements in gold bullion reserves, interest rates, and exchange rates, plotted alongside shifts in governmental policy regimes. It also presented a theoretical explanation of cycles based upon the accumulation and exhaustion of free loanable capital that fed into debates between economists like John Maynard Keynes (1883–1946) and Dennis H. Robertson (1890–1963) in the United Kingdom in the interwar period. Tugan-Baranovsky’s other influential work in economic history was The Russian Factory in the Nineteenth Century (1898), which documented various changes in industrial structure, such as the development of possessional factories and the rise and fall of cottage industry. Originally a legal Marxist, Tugan-Baranovsky’s economic methodology changed significantly after 1900, favoring an ethical basis to his socialism rather than a class-based approach, to the extent that by 1917 he was employing marginalist ideas in hypothetical planning models. During World War I (1914–1918), Tugan-Baranovsky analyzed the effects of various forms of war finance on future development prospects, and after Russia’s exit from the war he assisted in forming the Academy of Sciences in Kiev.

Dmitriev’s major work was his Economic Essays on Value, Competition, and Utility, first published separately in 1898 and 1902. One of the most well-known elements in these essays was the argument that unrestricted free
competition tended to raise production costs above their essential level, that is, above the lowest possible level for any given state of technique. According to Dmitriev, in the competitive battle for sales, accumulating stocks of commodities played the same role as a military arms race did between opposing powers during peacetime. Under free competition, the nonproductive expenditure on commodity storage was higher than under monopoly, due to the need for competing producers to maintain significant levels of dead stock, in fear of others stepping in and gaining market share. Hence free competition had additional economic costs in terms of wasted output, excess inventories, and redundant advertising. Dmitriev was Russia’s first mathematical economist, and he was also one of the most significant interpreters of the ideas of David Ricardo (1772–1823) within Russian borders.

Other significant Russian economists from the pre-revolutionary era included Struve, a leading member of the legal Marxists who (after emigration to the United States) became a trenchant critic of Stalinist economic policies; Mendeleev, the inventor of the periodic table of elements, a passionate advocate of industrial protectionism within Russian borders, and creator of the 1891 tariff; Chuprov, the leading representative of historical political economy in Moscow who emphasized the importance of knowledge and scientific invention to understanding economic progress; Bulgakov, a legal Marxist who stressed the international nature of capitalist development; Ivan K. Ozerov, a specialist in public finance and an expert on the structure of taxation in the United Kingdom and Germany; and Petr P. Migulin, a financial theorist who documented the history of currency policy within Russian borders, and also advocated monetary reforms designed to increase the stability of the ruble.

Perhaps the most famous and influential Russian/Ukrainian economist of all was Slutsky, who was also a noted mathematical statistician. He published two articles that had a great and lasting effect on the development of mainstream economics in the West. The first of these articles was “On the Theory of the Budget of the Consumer” (1915) and the second was “The Summation of Random Causes as the Source of Cyclic Processes” (1927). In the former, Slutsky divided the result of a change in demand induced by price changes into income and substitution effects, creating what is called the Slutsky equation as a basic tool of microeconomic analysis. In the latter article, Slutsky hypothesized that the summation of mutually independent chance events could generate sinusoidal periodicity, which might imitate the approximate regularity of business cycles, a process that became known in its statistical formulation as the Slutsky-Yule effect. Both of these significant contributions are still in use in economics textbooks today. Slutsky also wrote on the praxiological foundations of economics, analyzed the income received by the Soviet state from currency emission, and invented the concept of the stochastic limit. In the mid-1920s Slutsky transferred from Kiev to become a consultant in the Moscow Conjuncture Institute, which was a pioneering center for the study of business cycles and forecasting headed by Kondratiev.

Kondratiev himself is famous today as the originator of the idea of long cycles of economic development, that is, approximately fifty-year business cycles that are generated by both capital accumulation and technological change. In Kondratiev’s account, long cycles coexisted with medium-length economic cycles and also short cycles, within a three-cycle scheme of long-run capitalist development later adopted by Joseph Schumpeter (1883–1950). Kondratiev was initially an agricultural economist who worked on topics such as the effects of war and revolution on the functioning of Russian grain markets. During the New Economic Policy (NEP, 1921–1929) he developed a market-led industrialization strategy for the USSR based on the notion of encouraging the export of primary produce in order to fund capital imports, in direct opposition to Joseph Stalin’s (1879–1953) centrally planned strategy of import substitution. Kondratiev also developed a detailed planning methodology based on an indicative rather than an imperative approach that was fully realized in his plan for agriculture and forestry (1924–1928). Some of Kondratiev’s colleagues in the Conjuncture Institute, such as Albert L. Vainshtein (1882–1970) and Alexander A. Konyshev (1895–1982), survived the political purges of the mid-1930s and became well-known economists in their own right, Vainshtein for work on national wealth estimation and Konyshev for work on index number theory.

Other significant Russian economists from the NEP period included Chayanov, an agricultural economist who worked on the structure and motivating drive of peasant farms; Preobrazhensky, a Marxist who developed the notion of primitive socialist accumulation and analyzed the tributary relation between the peasant and the state sectors of the Soviet economy; Yurovsky, a neoclassical economist who mastered the 1922–1924 currency reform that successfully replaced the depreciating sovznak with the stable gold-backed chervonets; Groman and Bazarov, two leading members of the State Planning Agency (Gosplan) who documented the restoration processes occurring in the Soviet economy after the end of the Civil War and theorized various planning regularities that were significant to Soviet development policies; and Feldman, who developed an innovative two-sector model of economic growth that was disseminated in the West.

There is some noticeable continuity in the main themes and preoccupations of Russian/Soviet economics between the two golden periods identified above. Before
1917 both business cycles and national development were major topics that were addressed by many Russian economists, in particular in terms of documenting the links between the domestic economy and international capitalism. For example, a significant dispute arose over whether and to what extent Russian business cycles synchronized with those of western Europe, which was related to the degree of penetration of French, German, and British capital within Russian enterprises. After 1917 these general topics were still very significant, although the manner in which they were pursued within the framework of the development of the Soviet centrally planned economy was modified dramatically. National development was fostered not through international cooperation, but through centralized state planning. Another significant issue in discussing the development of Russian economics is its relation to economics being pursued in closely proximate countries such as Ukraine. Some of the most famous names in Russian economics, such as Tugan-Baranovsky and Slutsky, were born in Ukraine, only moving to Russia later in their lives. This dual identity makes the entity identified as “Russian economics” an amorphous grouping, especially when the influence of Western currents is added to the mix.

A significant by-product of the early Soviet period was the emigration of a number of important economists to Europe and the United States. Examples of such émigré economists were Sergei N. Prokopovich (1871–1955), Wasily W. Leontief (1906–1999), and also Struve. Leontief in particular had a significant impact on Western economics through his input-output approach to constructing a balance of the entire national economy. In another category of émigré was Roman Rosdolsky (1898–1967), a leading Marxian scholar and Ukrainian socialist. For a while, Rosdolsky was associated with the Marx-Engels Institute in Moscow. In his writings he was one of the first to highlight the relation between Marx’s published work in economics and G. W. F. Hegel’s *Science of Logic* (1812–1816) by comparing Marx’s *Capital* (1867–1894) with the *Grundrisse* (1857–1858). Rosdolsky also provided a reinterpretation of the Marxian reproduction schemes in which they were seen as only an abstraction of capitalist logic, not a concrete model of actual historical development.

**THE STALIN ERA AND AFTER**

After 1929 Stalin’s ascent to power led to the destruction of the cadre of brilliant Russian economists that had prospered so notably in the golden era. Some, like Kondratiev and Yurovsky, were jailed on fictitious charges and eventually executed, while others, like Slutsky, were forced to leave the subject of economics completely for more neutral areas of research such as statistics. Even so, by the end of the 1930s a new school of mathematical economists led by Leonid V. Kantorovich (1912–1986), Vasilii S. Nemchinov (1894–1964), and Viktor V. Novozhilov (1892–1970) had reintroduced neoclassical ideas in a camouflaged form through the notion of an optimal plan and the idea of a system of optimally functioning economy (SOFE). This mathematical school provided the basis for many of the reform efforts directed at improving the performance of the Soviet economy that occurred sporadically throughout the 1950s and 1960s, but entrenched bureaucratic impediments often hindered the implementation of these attempted reforms. Although Kantorovich was awarded the Nobel Prize for economics in 1975, the 1970s are often described as a period of stagnation in the Soviet economy and also in Soviet economics.

In the Mikhail Gorbachev era (1985–1991), economic reformers like Abel Aganbegyan began to win ascendancy, but were quickly outflanked by a more radical group of pro-market thinkers who desired the dismantling of the Soviet economy and the creation of an entirely new market-based system. This group was triumphant after 1989, leading to full-scale privatization and price liberalization in the early 1990s. The pro-market reform program that was adopted was heavily influenced by Western economists such as Jeffrey Sachs and Richard Layard, and also by Eastern European converts to market economics such as Janos Kornai. Transforming property ownership and achieving free prices were given immediate priority, leaving the legal and institutional environment to fend for itself. Macroeconomic stabilization took some time to achieve, with a significant banking crisis occurring in Russia in 1998. In addition, organized crime grew to occupy a more central position in many post-Soviet economies than it did in the “mature” capitalist economies of the West.

Consequently, whether the transition to a market economy undertaken in Russia after 1989 is regarded as a complete success depends at least in part upon the perspective adopted. Dramatic changes and many improvements have undoubtedly taken place, with some definite winners and also some noticeable losers, but whether the post-Soviet form of mafia capitalism is (all things considered) superior in every respect to the previously existing version of bureaucratic socialism is a debatable point. In terms of the influence of market reform on Russian economics as a discipline, mainstream Western economic theory came to occupy a similar position in Russian universities as it does in the West. The Soviet variety of Marxist economics was totally discredited in the process, but this only had a tenuous relation to the actual ideas of Karl Marx in the first place.

 RUSSIAN FEDERATION

According to international law, the Russian Federation from 1992 is the successor state of the Union of Soviet Socialist Republics (USSR), which was created after the First Russian Revolution in October 1917. The USSR was established formally in 1922 and was the successor state of the Russian Empire under the tsarist rule of the Romanov family from 1721.

The founder of the Soviet Union was Vladimir Ilyich Lenin (1870–1924). On the ideological basis of Marxism-Leninism, the Soviet Union existed for seventy-four years as an alternative Eastern political and economic regime, competing with Western democracy and the market economies of the “First World” and thus constituting the so-called Second World. In 1928 the successor of Lenin as leader of the Communist Party was Joseph Stalin (meaning “man of steel”; 1879–1953) from Georgia. The Soviet Union moved from Leninist principles (1922–1927) to a totalitarian Stalinist regime, which lasted from 1928 until Stalin’s death in 1953. Stalin was followed by Nikita Khrushchev, the Communist leader until 1964, and Leonid Brezhnev from 1964 to 1982. The Brezhnev era was much less radical than the Stalinist era—with its millions of regime victims—and produced a certain degree of social, economic, and political stability as well as stagnation. After the end of the long Brezhnev era, two party leaders, Yuri Andropov and Konstantin Chernenko, had short terms in office until March 1985.

The last important political leader of the USSR after Lenin, Stalin, Khrushchev, and Brezhnev was Mikhail Sergeevich Gorbachev, who came into power in 1985. His policy was to overcome the general stagnation by introducing decisive structural reforms into the Communist economic and political regime. Gorbachev attempted to modernize the USSR so that it could compete successfully with the Western world of democracy and free markets, but it failed in the end. His wide-ranging reforms of the Soviet Union had three main elements. The most important reform was perestroika, a structural reform of the planned economy, and glasnost, the acceleration of these economic changes. The second strand of political reforms focused on glasnost, or public openness and transparency about the Stalinist past—with political terror, genocide, and mass murder—and the political history of the USSR. Within these broad areas of economic and political change, Gorbachev started public campaigns against alcoholism and corruption, which proved to be rather unpopular in Soviet society. The third dimension of these deep reforms was demokratisatsiya, which tried to democratize Soviet society without the introduction of democracy and retaining the Communist one-party state.

In August 1991 conservative Communist forces attempted a coup d’état to stop the structural reforms of the Soviet system that Gorbachev initiated and directed. The Communist coup was stopped within three days by Boris Yeltsin (1931–2007). This attempt to stop the disintegration of the USSR accelerated it. The Soviet Union ceased to exist on December 31, 1991.

The population of the USSR before the final breakdown encompassed 286 million Soviet citizens. The Russian Federation as successor state lost 139 million former Soviet citizens to other Newly Independent States (NIS) and had an initial population of 147 million inhabitants. During the 1990s, the Russian Federation experienced a dramatic decrease in life expectancy, especially among Russian men, and had a population of 143 million citizens in 2005. The Russian demographic crisis has almost been offset by immigration from other former Soviet Republics into the Russian Federation. In the early twenty-first century the Russian Federation is structured into seven federal districts: the Central District around the capital city Moscow, the Northwestern District with Saint Petersburg, the South District that includes the northern Caucasus, the Volga District, the Ural District, the Siberia District, and the Far Eastern District. Russia consists of eighty-six regions and republics, which are integrated into these seven large federal districts.
In June 1991 Yeltsin became president of Russia as part of the Soviet Union after the first Russian presidential elections with 57.3% of the vote. In 1996 he was elected as the first president of an independent Russia with 53.8% of the valid vote. During his eight years in power, Yeltsin had the difficult task of ending the old political and economic Soviet regime and commencing the transformation toward a democratic system and a market economy in a vast country that covers 11 time zones and about 6.6 million square miles. Weakened by health and alcohol problems, Yeltsin resigned from office on December 31, 1999.

Vladimir Putin (b. 1952) became acting president of Russia on January 1, 2000. He won 52.94% of the valid votes in the Russian presidential elections on March 26, 2000. Between 2000 and 2007 he created a hybrid political system, which combines elements of a democratic regime with those of an autocratic regime. The Putin regime is characterized by centralization of power (e.g., appointment of regional governors instead of regional elections), absence of a full rule of law, lack of separation of powers, restricted human and political rights, and suppression of electronic media. President Putin weakened the political powers of the Russian national parliament, the Duma, as well as the Russian party system by favoring a new presidential party with the name United Russia. The Putin era has transformed the Russian Federation into a political system with a historically unique mixture of democratic and autocratic elements. Hence the historical path of Russia toward democracy or autocracy will be decided after the Russian presidential elections in 2008. The Second Russian Revolution, which began in August 1991 with an attempted coup to return to a Communist regime as well as the dissolution of the Soviet Union, has not yet reached a historical conclusion.

Russian Revolution

The revolutionary crises of 1917 had their origins in the deep social and political polarization in Russian society that intensified in the first decades of the twentieth century. Peasants suffered from land shortages, periodic hunger, high incidence of disease and early mortality, the burdens of taxation and rents, and military recruitment. Factory workers and artisans lived in squalid tenements or hovels and worked long hours in dangerous conditions. The better-off middle and upper classes were not only more literate, educated, and socially mobile than the peasants, but lived under a different code of law and enjoyed privileges that the ordinary villagers did not. Through the nineteenth century politically-engaged Russian intellectuals gravitated from liberalism and moderation toward revolutionary socialism, at first oriented toward the peasants (populism or narodnichestvo) and later, by the 1890s, increasingly focused on the urban workers (Marxism, Social Democracy).

Marxism provided a sociological and economic framework for Russian activists, a view of the way the world worked under capitalism and the European future toward which Russia was headed. Unlike the pro-peasant socialists or populists, who eventually formed the Socialist Revolutionary Party, Marxists believed that Russia could not avoid industrialization and capitalism and had to pass through two successive revolutions, a bourgeois-democratic revolution followed by a proletarian-socialist revolution in which the working people would come to power to build socialism. In 1903 the principal Marxist organization, the Russian Social Democratic Workers’ Party, split into two rival factions, the moderate Mensheviks, who were usually more willing to work with other democratic parties, like the populists and liberals, and the more radical Bolsheviks, led by Vladimir Lenin (1870–1924), who generally favored a more rapid transition to the socialist revolution.

However wide the social divide between the state and society in the decades before World War I (1914–1918), the war expanded the gulf and radicalized the workers and peasants. Millions of peasants were turned into soldiers,
given guns, and shown that a wider world existed beyond
the edges of the village. The February Revolution began
on February 23 [Julian calendar] (March 8 on the
Gregorian calendar, International Women’s Day) with working-class women demanding bread in the cold, dark
streets of Petrograd. Within days, hundreds of thousands
of Petrograd workers were in the streets, and when Cossacks and ordinary soldiers refused to fire on the
crowds, the strike turned into a revolution. The tsar,
Nicholas II (1894–1917), abdicated, as did his brother,
Grand Duke Mikhail, and the monarchy came to an end.

On March 1 (14), middle-class members of the duma
formed a provisional government, headed by Prince
Georgii Lvov and including leaders of the major liberal
and conservative parties. At the same time, workers and
soldiers formed their own representative bodies, the soviets
(councils) of workers’ and soldiers’ deputies, for
though their leaders were unwilling to take power on their
own, they were suspicious of the intentions of the “bourgeois”
members of the provisional government. Russia
now had not one unchallenged government but “dual
power,” two competing authorities. In April, the leaders of
the Soviet confronted Foreign Minister Paul Miliukov,
who insisted on Russia’s imperial claims to Constanti-
nopole and the Dardanelles. Workers and soldiers poured
into the streets, and forced Miliukov to resign. Moderate
socialist leaders of the Soviet reluctantly joined the “bourgeois”
government, but in the next six months the various
coalition governments were unable either to end the world
war or to alleviate the social divisions in Russian society.

While the government wavered, the Bolsheviks won
majorities in the factory committees and successfully agi-
tated against the war at the fronts. Lenin, who had
returned to Russia from exile in Switzerland in April,
staked out a radical program for transferring all power to
the soviets, ending the war, and moving the revolution
rapidly into a socialist phase. The Bolsheviks were the
only major party that provided a clear alternative to the
government and their moderate socialist allies.

To please the Western Allies and contribute to the
war effort against the Central Powers, Minister of War
Alexander Kerensky launched a disastrous offensive
against the enemy in June, but as news of Russian defeats
reached the capital, workers, sailors, and soldiers demonstr-
ated against the war and the government, even calling
on the Soviet to take power in its own name. The moder-
ate socialists refused, while militant elements supporting
the Bolsheviks pushed to seize power. When order was
restored by troops loyal to the government and soviets,
Lenin was forced to go into hiding in Finland. Lvov
resigned, and Kerensky formed a new coalition govern-
ment. Liberal and conservative forces became more wary
of the lower classes and called for an authoritarian govern-
ment to restore order. The clumsy attempt by General
Lavr Kornilov to establish a new authority, however,
ended with the lower classes moving swiftly toward the
Bolsheviks and electing them the majority party in both
the Petrograd and Moscow soviets by early September.

In the second half of October, the Military-
Revolutionary Committee of the Petrograd Soviet, led by
Leon Trotsky (1879–1940), began establishing its author-
ity over the garrisons of the city. On the morning of
October 24 (November 6), Kerensky moved to suppress
the Bolsheviks and prevent the insurrection that everyone
knew was coming. In the crucial hours, however, the
prime minister found his support weak or non-existent.
Though workers did not actively participate in the insur-
rection, the Bolsheviks found the military muscle to take
power. By dawn on October 25 (November 7) the city was
in the hands of the Military-Revolutionary Committee,
and Lenin went before the Second Congress of Soviets
and declared that power had passed to the soviets. When
the moderate socialists, the Mensheviks and Right
Socialist Revolutionaries, protested the Bolshevik seizure
of power and walked out of the Congress, they essentially
left the Bolsheviks and Left Socialist Revolutionaries to
form a new government. Though Lenin preferred a one-
party government, within a month he conceded seats to
the Left Socialist Revolutionaries, and until March 1918
Soviet Russia had a Left Socialist coalition government.

In November 1917 elections were held to a
Constituent Assembly, a kind of founding congress for the
new republic. The Bolsheviks failed to win a majority,
while the Right Socialist Revolutionaries emerged with
the largest plurality. After allowing a single day’s meeting
(January 5 [18], 1918), however, the Soviet government
dispersed the Constituent Assembly, Russia’s most freely
elected parliamentary body until the early 1990s. In the
ensuing civil war the communists did not hesitate to use
violence and terror, and as atrocities occurred on both
sides, much of the democratic promise of the revolution
of 1917 was lost.

RYBCZYNSKI THEOREM

The Rybczynski theorem, along with the Stolper-Samuelson, factor-price equalization, and Heckscher-Ohlin theorems, is one of four key propositions describing the properties of the standard Heckscher-Ohlin model with two goods and two factors. The Polish-born economist Tadeusz M. Rybczynski’s (1923–1998) paper, “Factor Endowment and Relative Commodity Prices” (1955), relates changes in an economy’s factor supplies to resulting changes in equilibrium outputs and prices.

The simplest version of the Heckscher-Ohlin model assumes that two goods, say autos and textiles, are produced using the same two factor inputs, say labor and capital, but in proportions that differ across the two industries. If the auto industry uses a higher ratio of capital to labor, it is termed the capital-intensive industry, while the textile industry is termed labor-intensive. Under the usual assumptions of the model, an increase in the supply of either factor, holding constant the supply of the other, results in an outward shift of the production possibility frontier. Thus, the economy can now produce more of both goods, so that most economists prior to Rybczynski’s contribution assumed that this kind of biased growth would result in higher equilibrium outputs of each good, though with relatively greater growth of the industry that uses more of the growing factor.

Rybczynski’s surprising result is that a given percentage increase in the supply of one factor, say capital, holding constant the supply of the second factor (labor) as well as the relative price of the two goods, must result in a still larger percentage increase in the equilibrium output of the good that is capital-intensive in production (autos), and an absolute decrease in the equilibrium output of the good that is labor-intensive (textiles). The result also requires that the economy produce some of each good in both the equilibrium prior to the change in factor supply and the final equilibrium following the change. Rybczynski’s proof makes use of the box diagram as applied for the first time to production by Wolfgang Stolper and Paul A. Samuelson in their landmark paper, “Protection and Real Wages” (1941), which presented what is now known as the Stolper-Samuelson theorem. Moreover, Rybczynski builds on Stolper and Samuelson’s key insight concerning the basic two-good, two-factor version of the Heckscher-Ohlin model—that the relative price of the two goods uniquely determines factor prices and thus factor proportions.

In general, an economy can adjust to an increase in the supply of capital, holding constant the supply of labor, through some combination of capital-deepening and a changed mix of outputs. This alternative formulation of the Rybczynski theorem was provided by Ronald Jones in his 1965 paper, “The Structure of Simple General Equilibrium Models,” which offers the first integrated treatment, as well as a number of generalizations, of the four key theorems of the Heckscher-Ohlin model. To the extent that more capital results in a reduction in its relative cost to producers, firms in both sectors will now opt for a higher ratio of capital to labor. But the Stolper-Samuelson theorem implies that with output prices fixed and both goods produced, factor prices and thus cost-minimizing capital-labor ratios must remain unchanged in the new equilibrium. Thus, the adjustment is achieved entirely through a change in the mix of outputs. Expansion of the capital-intensive industry allows additional capital to be employed, but more labor is also required to maintain that industry’s unchanged ratio of capital to labor. This labor (plus additional capital) must be obtained through a contraction in the equilibrium output of the labor-intensive industry, which releases a relatively higher ratio of labor to capital than is required for expansion of the capital-intensive industry. This allows the additional capital to be absorbed at constant factor prices.

The Rybczynski theorem, by indicating what would be produced at unchanged output prices, has clear implications for effects of biased factor growth on actual prices in the resulting equilibrium. Assuming that both goods are normal in consumption—that is, that as incomes rise more of each will be demanded—growth in the supply of capital necessarily means a drop in the relative prices of
autos for a closed economy and, not surprisingly, an associated decline in the return to capital, the auto industry’s intensively used factor. Moreover, as Stolper and Samuelson demonstrated earlier, the decline is not merely relative; capital’s return must fall in real terms. Likewise, the return to labor, the factor now relatively scarcer, must rise in real terms. For an open economy, the Rybczynski theorem allows predictions about the resulting changes in a country’s equilibrium trade volume and terms of trade. As the stock of capital grows, desired trade at given terms of trade will increase (decrease) if the country is capital-abundant (labor-abundant) relative to its trading partners. An expansion of the capital stock will thus lead to deterioration (improvement) in the country’s terms of trade. Corresponding results hold for an expansion of labor with capital held constant.

Despite its stark assumptions, the Rybczynski theorem, especially as later generalized by Jones, provides powerful insights into the likely consequences of biased factor growth. Like the supply and demand curves of partial-equilibrium analysis, the simple Heckscher-Ohlin model provides the first back-of-the-envelope attack on a wide range of questions. Together with the other theorems of the Heckscher-Ohlin model, the stripped-down basic version of the Rybczynski theorem has become an essential part of the intellectual toolkit of every international economist.

Rachel McCulloch
SADAT, ANWAR
1918–1981

Born in Mit Abul Kom, a town north of Cairo, Egypt, Sadat was one of the first students to graduate from a British military school. On graduating, he was posted to a remote government base where he met Gamal Abdel Nasser (1918–1970), a charismatic army major who was to become the nationalist leader of Egypt. They maintained a lifelong friendship. From 1942 on, Nasser secretly organized young cadets and officers to promote a republican, anti-British patriotic movement. The movement’s radical ideas were also directed against the corrupt monarchy of King Farouk (1920–1965), whose profligacy and incompetence were partly held responsible for the failures of the Egyptian army against Israel in 1948. In response to these military and political failures, Nasser’s group evolved into the Free Officers Movement, which staged a coup on July 23, 1952, against Farouk. Sadat, who became Nasser’s public relations minister, remained under the shadow of Nasser during the dramatic events in modern Egyptian history—the Suez crisis (1956) and the Six-Day War (1967)—until Nasser’s death in September 1970.

RISE TO INTERNATIONAL PROMINENCE

Sadat was relatively unknown in international politics, despite the many positions he had held during Nasser’s period—minister of state (1954), secretary to the National Union (1959), president of the parliament (1960–1968), and vice president and member of the Presidential Council (1964). In his attempt to emulate Nasser, he initially adopted a stridently aggressive stance against Israel, including the surprise attack in the Yom Kippur War of October 1973. The war ended in stalemate; with the Egyptian economy in crisis, Sadat adopted a diplomatic approach to Israel, launching the Sadat Initiative in 1977. This started a peace process that led to the Camp David talks in September 1978 with U.S. President Jimmy Carter and Israeli prime minister Menachem Begin. The peace treaty that was signed in March 1979 involved the return of the Sinai to Egypt, the creation of demilitarized zones, and some autonomy for a Palestinian administration. Both Begin and Sadat received the Nobel Peace Prize, but the peace agreement was opposed by the Palestine Liberation Organization, several Arab states, and right-wing elements in Israel.

DOMESTIC PROBLEMS

Opposition from within Egypt came from Muslim fundamentalists. Sadat attempted to co-opt radical Muslim groups, including the Muslim Brothers, whom Nasser had exiled. He realized that the extreme poverty of the peasantry and urban working class created a breeding ground for religious and political radicalism. To stimulate the Egyptian economy, Sadat in 1975 sought to expand the private sector and to reduce the old Soviet-style economy and state bureaucracy. This economic opening (infitah) was combined with a policy of supporting moderate Muslim intellectuals such as Omar Telmesani, who began...
to publish *Al Dawa* (Call to Islam) in 1976. In return for their political support, Sadat allowed these religious intellectuals considerable cultural freedom.

This political pact began to disintegrate in 1977 when riots broke out in response to the negative consequences of the “open-door” economic policy and a radical group called the Society of Muslims (*Al Takfir wa-l Hijra*) defied the government by kidnapping and murdering a cleric. Sadat’s peace process, which involved some recognition of Israeli sovereignty, was rejected by both moderate and radical elements of the Muslim community. The radicals, who became known generally as *takfir*—a devout Muslim who excommunicates other Muslims who are seen to be lapsed—spread their message through much of the Arab world. These movements accepted the teaching of Sayyid Qutb (1906–1966), who, as the founder of the Muslim Brothers, had preached the necessity of violent *jihad* against unbelievers and who was hanged for an alleged plot against Nasser.

In response to this radicalization, Sadat dissolved the Egyptian Students Union and brought a number of key activists to trial. Some 1,600 people were arrested, resulting in significant international and domestic criticism. He also attacked the Coptic community, forcing the Coptic Pope Shenouda III into exile (he was eventually restored by President Hosni Mubarak in 1985). As a result of this political crackdown, the radicals became a clandestine movement among the underclass of the slums of Cairo, declaring a war against Sadat and the moderate clerics who were accused of apostasy. Sadat was assassinated on October 6, 1981, during the yearly 6 October 1973 victory parade by Muslim fundamentalists inside the army. He was buried in the unknown soldier memorial in Cairo and was succeeded by Mubarak as president.

The problems facing Egypt in Sadat’s time continue to dominate Egyptian politics. The state bureaucracies remain firmly in control of the economy and, despite President Mubarak’s moderate reforms and the recent success of the Egyptian stock market, a democratic culture has been slow to develop. The Muslim Brothers are excluded from parliamentary politics because they are still regarded as an illegal organization. A fragile peace with Israel has, however, been sustained because both governments regard Hamas (*Harakat al-Muqawama al-Islamiyya*) in the West Bank and Hizbullah (the Iranian-backed Party of God) as a threat. Periodic attacks on tourists, Copts, and members of the government have also curtailed the growth of the tourist industry. Between 1993 and 1997, Mubarak responded with ruthless oppression against members of the radical Gamaat Islamiya. In retrospect, Sadat’s era was progressive in attempting to secure peace and reform the economy, but he left behind a legacy of authoritarianism.

SAINT-CLAIR, ANDREW 1530–1609

One of the most influential cultural anthropologists of the latter part of the twentieth century, Marshall Sahlins has written seminal works on economic anthropology, social and cultural theory, and the relation of culture and history. In his earliest writings he sought to clarify the social-evolutionist theory of Leslie White, his University of Michigan teacher, but he soon came to reject White’s evolutionaryism and technological determinism. In his mature works, he has elaborated a sophisticated reworking of Claude Lévi-Strauss’s structuralism, one that is antithetical to reductionism of all kinds in the study of culture.

In his book *Stone Age Economics* (1972), Sahlins criticized the evolutionist ranking of societies on universalistic criteria such as the intensity of economic production. Influenced by Karl Polanyi, Sahlins argued that economic systems are culturally ordered, serving different ends in different societies. For example, hunter-gatherer societies may seem poor because the people have few possessions, but in fact they enjoy a kind of material plenty precisely by virtue of being unencumbered by things that impede their mobility. Traditionally, such people subsisted on wild foods, and when these grew scarce in one region, they could easily pack up and move to a richer one. Indeed, to the extent that poverty is a social status and a matter of

SAHLINS, MARSHALL 1930–

One of the most influential cultural anthropologists of the latter part of the twentieth century, Marshall Sahlins has written seminal works on economic anthropology, social and cultural theory, and the relation of culture and history. In his earliest writings he sought to clarify the social-evolutionist theory of Leslie White, his University of Michigan teacher, but he soon came to reject White’s evolutionaryism and technological determinism. In his mature works, he has elaborated a sophisticated reworking of Claude Lévi-Strauss’s structuralism, one that is antithetical to reductionism of all kinds in the study of culture.

In his book *Stone Age Economics* (1972), Sahlins criticized the evolutionist ranking of societies on universalistic criteria such as the intensity of economic production. Influenced by Karl Polanyi, Sahlins argued that economic systems are culturally ordered, serving different ends in different societies. For example, hunter-gatherer societies may seem poor because the people have few possessions, but in fact they enjoy a kind of material plenty precisely by virtue of being unencumbered by things that impede their mobility. Traditionally, such people subsisted on wild foods, and when these grew scarce in one region, they could easily pack up and move to a richer one. Indeed, to the extent that poverty is a social status and a matter of
wanting more than one has, hunter-gatherers have far less poverty than do the grossly unequal societies of advanced civilization, since their culture leads them to share scarce resources (like meat from the hunt) rather than possessing or consuming them individually. Thus, they exemplify a “Zen road to affluence,” or a “want not, lack not” philosophy that shows that the naturalized Western conception of mankind as fundamentally acquisitive and driven by fear of scarcity is ethnocentric (Sahlins 1972, pp. 2, 11).

In *Culture and Practical Reason* (1976), Sahlins took these arguments farther, offering a philosophically compelling, general critique of anthropological theories that explain social and cultural phenomena by appealing to material or functional causes outside the culture itself. Because practical utility and functionality are themselves always relative to particular cultural modes of existence, Sahlins wrote that it is wrong to conceive of them as external to the symbolically organized order of culture.

Structuralism’s great shortcoming has been its artificial separation of culture’s abstract symbolic structure from the real historical events that perpetuate and transform it. But these are reintegrated in Sahlins’s theory of structural history. Since people necessarily act according to their culturally presupposed categories and values, “history is culturally ordered, differently so in different societies” (Sahlins 1985, p. vii). Sometimes actions have unexpected outcomes, however, that can lead people to reconsider their conventionally held cultural meanings. Thus, cultural orders themselves are historical, partly formed and transformed by events. In his writings since 1980, Sahlins developed this theory through extended historical studies of intercultural contact in early colonial Hawaii and Fiji, as well as in the transpacific trade connecting Britain, China, Hawaii, and the Northwest Coast of America in the eighteenth and nineteenth centuries.

A brilliant polemicist, Sahlins has participated throughout his career in important debates on such matters as color perception, sociobiology, world-systems theory, and postmodernism in anthropology. Perhaps the most famous of these was his debate with Gananath Obeyesekere on native rationality and the power of myths. This exchange centered on Sahlins’s historical account of the European explorer Captain Cook’s visit to Hawaii in 1779, and particularly on the question of whether he was viewed at the time by native priests as a manifestation of a Hawaiian god, Lono. The larger intellectual issue this raised was the politics of depicting cultural difference. Obeyesekere accused Sahlins of exoticizing the Hawaiians and perpetuating a European colonial myth in which irrational natives are naïvely given to mistaking Europeans for gods. In responding, Sahlins marshaled impressive evidence that Cook was treated as Lono in historical fact, and he argued that it is a greater denigration of other peoples to submerge their cultures’ distinctive rationalities under a well-intentioned but ethnocentric portrayal as being essentially just like one’s own. Some European colonial writers undoubtedly disparaged cultural Others for confusing certain men with their gods, but these Others may not have shared the European presumption that gods and men are (with one singular exception) nonoverlapping categories, highly distant from one another.

**SAID, EDWARD 1935–2003**

Edward Said is recognized as one of the most influential literary critics of the last quarter of the twentieth century. Said’s contributions to postcolonial and critical theory, the humanities, cultural studies, social geography, and the social sciences evade easy categorization given the startling breadth and range of his thought. Influenced by Michel Foucault, Giambattista Vico, Georg Lukács, Antonio Gramsci, Frantz Fanon, and Theodor Adorno and a self-proclaimed admirer of Sigmund Freud, Said was among the first to introduce American academic audiences to structuralism, poststructuralism, and to a lesser extent deconstruction.

A critical scholar nevertheless deeply committed to humanism, Said was also a public intellectual known for
his eloquent commitment to Palestinian self-determination. Born in Jerusalem, Said fled with his family to Cairo in 1948 and a few years later relocated to the United States. He studied at Princeton and then at Harvard, where he wrote a PhD dissertation on Joseph Conrad, then joined Columbia in 1963. Unexpectedly moved by the profound injustice of the dispossession of the Palestinians, with whom he increasingly identified as an exiled intellectual, he found the Six Days War of 1967 a politicizing moment and significant turning point in his life. Over the next several decades Said became a frequent commentator on U.S. foreign policy and Middle Eastern politics. He was a regular contributor to Al-Hayat (a London-based Arab daily) and Al-Abram Weekly (an Egyptian daily) as well as serving as the music critic for the Nation.

Said is best known for his groundbreaking work Orientalism (1978). Widely acknowledged as a cornerstone text for postcolonial studies, this acclaimed work has also had profound influences on social geography, cultural studies, and radical history. Drawing on Foucault's notion of discourse, Said exposes Orientalism as a Western system of thought that is linked to imperialism and the establishment of cultural hegemony and is an essentializing discourse that effectively produces the “Orient” as the West’s “other.” Orientalism observes the West observing the Middle East, Arabs, and Islam, and two further volumes in the trilogy, The Question of Palestine (1979) and Covering Islam (1981), sustain this focus. In the trilogy's 1993 sequel, Culture and Imperialism, Said expands these insights to explore a more generalized relationship between cultural production and empire. In the latter text he draws on European writing (and one musical piece, Verdi’s Aida) on Africa, India, the Far East, Australia, and the Caribbean to show how an imperialist imagination is embedded in cultural production and how cultures of resistance to imperialism emerge in a context of decolonization.

The Question of Palestine (1979) was Said’s first major text on Palestine, and in it he endeavors to establish a broadly representative Palestinian perspective for a Western, and primarily an American, audience. This particular text documents the historical and political dispossession and erasure of the Palestinians by Zionist colonization and thus differs distinctly from Orientalism, which drew mainly on literary texts. However, in method Said effectively demonstrates that a hegemonic cultural attitude toward Islam, the Arabs, and the Orient is what makes the ongoing colonial violence against the Palestinians a possibility. Thus the “Palestinian problem” is a materialized effect of Orientalism. Covering Islam proceeds similarly but with a focus on the Western media’s role in representing, and imagining, Islam. Other books on Palestine include The Politics of Dispossession (1994), After the Last Sky (1986), Blaming the Victims (1988), and The End of the Peace Process (2000).

Said’s wide-ranging and often controversial thought is rooted in literary theory. His dissertation on Joseph Conrad’s letters was influenced by the Geneva school, a vein of literary criticism rooted in the phenomenological thought of Husserl and Merleau-Ponty, and became his first book, Joseph Conrad and the Fiction of Autobiography (1966). For Said, Conrad’s letters revealed the uncertainty, difficulty, and reflexive struggle of a self-exiled Pole, an articulate writer who was nevertheless disoriented and not quite sure of his place in the world. An interest in the condition of the exiled writer, a theme that continues through his life’s work, is palpably present in this first book.

Said’s second book, Beginnings: Intention and Method (1975), began to establish his reputation as one of America’s foremost literary critics, as the text drew on contemporary French theory in its concerns to shift from theological “origins” to the problem of a secular “beginning” point for critical theory, where human action makes history, and a history of change. The text explores the relation of literature to philosophy, psychology, and critical theory through an engagement with the writings of Freud, Foucault, Freidrich Nietzsche, and Vico as well as Jacques Lacan, Jacques Derrida, Giles Deleuze, and Claude Lévi-Strauss.

The World, the Text, and the Critic (1983) is an early “bridging” text of Said’s thought. This integrative and synthetic work is interested in the material contexts—the “worldliness”—of writing. Increasingly impatient with an academic domestication of poststructuralist and deconstructive theories of textuality, Said argues that critical scholarship must be situated in material struggles so that the critic does not lose sight of the political context in which intellectual pursuits become possible. The text is an early critique of the narrow confines of academic disciplinary, which Said argues is implicated in a tamed specialization of intellectual inquiry. His deep commitments to humanism are evident in this text, and he returns again to these themes in a series of lectures given at Columbia University, posthumously published under the title Humanism and Democratic Criticism (2004). In this text Said reflects on the tensions between humanist, structuralist, and poststructuralist modes, and he suggests that although humanism is critiqued as essentializing and totalizing, a commitment to the humanistic ideals of justice and equality are nevertheless crucial for a critical scholar. Throughout his vast and disparate body of work, Said maintains a critical posture within humanism, a “contrapuntal” awareness perhaps made possible by the condition of being an exilic, border intellectual.

A talented pianist, Said also wrote extensively on music’s relation to society, and his critical writings often

**SALIENCE, MORTALITY**

Mortality salience is a psychological state in which thoughts of one's death are prominent, or salient, in the individual’s conscious mind. The concept was developed by Jeff Greenberg, Tom Pyszczynski, and Sheldon Solomon in 1986 to test hypotheses derived from terror management theory. The theory proposes that the fear of death motivates people to maintain faith in cultural worldviews that makes life seem meaningful and to be enduringly significant contributors to that meaningful reality. In this way, people can believe they will endure beyond their own deaths; this belief in turn helps people control their terror of death.

Greenberg and his colleagues proposed that if the theory is correct, then increasing mortality salience should intensify people’s support of their own cultural worldview and striving for self-worth within the context of that worldview. Mortality may become salient in many natural contexts, including following acts of terrorism or war, natural disasters, reading or watching news or crime stories, witnessing automobile accidents, the death of a close friend or family member, or being in close proximity to a cemetery. The most common method to increase mortality salience in experiments is to ask participants to respond to the following: “Please describe the emotions the thought of your own death arouses in you”; and “Jot down, as specifically as you can, what you think will happen to you physically as you die and once you are physically dead.”

The first study utilizing this mortality salience induction found that mortality salience led municipal court judges to recommend a much higher bond in a hypothetical prostitution case. This finding supports terror management theory because it shows that mortality salience encouraged the judges to uphold their worldview by punishing someone who violated the morals of that worldview. Subsequent studies found that mortality salience leads people to react positively to anyone who supports one's worldview and negatively to anyone who violates it. Further research has found that mortality salience affects a wide range of judgments and behaviors that preserve faith in either one's worldview or one's self-esteem.

More than 200 studies have made mortality salient, using various methods and comparing mortality salience to many control conditions. Mortality salience has been increased by exposure to death anxiety questionnaires, gory accident videos, and proximity to funeral parlors and cemeteries. Control conditions have reminded participants of neutral topics and aversive topics such as failure, uncertainty, pain, and social exclusion. These findings have supported the specific role of thoughts about death in mortality salience effects.

Research exploring the cognitive processes activated by mortality salience has shown that mortality salience first leads people to distract themselves from thoughts of death. However, after a delay, thoughts of death return to the fringes of consciousness; this is when worldview and self-esteem—bolstering effects of mortality salience occur. Similar effects occur after exposure to very quick subliminal flashes of death-related words on a computer screen. These words appear for 28 milliseconds in between two easily visible neutral words. Because research participants are not aware of them, these briefly flashed words bring death thoughts close to consciousness without making mortality salient. This work suggests that the problem of death exerts its influence outside of conscious awareness.

Mortality salience research supports terror management theory and by so doing suggests that because of the need to control mortality concerns, naturally occurring reminders of death may contribute to nationalism, prejudice, and intergroup aggression, as well as pro-social behavior and valued cultural achievements.

The derisive term Sambo refers to African American males in a manner that is commonly viewed as racist and unacceptable. The long career of the Sambo stereotype is an important window into the history of black-white U.S. race relations. The term itself is a form of denigration and represents a stereotype that has been used variously to justify the inhumane treatment of slaves, provide a rationale for Jim Crow segregation, and, most often, to pander to the basest racist impulses in the United States to entertain white popular audiences. The Sambo stereotype has had several iterations in U.S. popular culture, ranging from children’s literature to minstrel shows of the slavery and post–Civil War eras, radio, motion pictures, television, and dining establishments. In addition, the Sambo stereotype also has a controversial career in the work of academics who studied slavery, particularly Stanley Elkin’s 1959 publication Slavery. This characterization of black men as passive buffoons was creatively challenged in Spike Lee’s 2000 movie Bamboozled.

**THE ORIGINS OF SAMBO**

One of the first representations of Sambo appeared in an 1808 short story by Edmund Botsford titled “Sambo and Toney: A Dialogue in Three Parts.” Much of the Sambo stereotype—subservient, ignorant, and linguistically challenged—was presented in its full form in this early iteration. The story was intended to convey a supposedly accurate conversation between two slaves:

Sambo: Yes, thank God brother Toney, my master good, and I like up the country and cotton planting very well—you got a good master, Toney?

Toney: So fo, he do, he give us victual enough and good clothes but he make us work devilish hard….

Sambo: Well then, why you complain and say devilish hard, you know what devilish mean, Toney? devilish is something wicked, I fear you use fuch words, you wicked too, Toney.

Toney: What you call wicked, Sambo?

This dialogue is set in the slave South—though according to Botsford, “Fambo” might be a more appropriate spelling—but the last line is not far from a 1980s equivalent uttered in the television program Diff’rent Strokes: “Whatchoo talkin’ ‘bout, Willis?” A continuous thread of racism pervades U.S. popular culture, and to this day African American actors are often relegated to playing the fool.

**SAMBO AND THE MINSTREL SHOW**

The Sambo stereotype found its largest audience with the rise of minstrel shows in the 1830s. It was the minstrel show that popularized these caricatures of black slaves with white, working-class audiences. Sambo the stage performer was popularized when a white entertainer named Thomas “Daddy” Rice created the character known as Jim Crow. The accompanying song, entitled “Jump Jim Crow,” was penned by Rice and utilized the same exaggerated mispronunciations:

Weel about and turn about and do jis so,
Eb’ry time I weel about and jump Jim Crow.

Rice claimed he modeled the character after an old black man he observed in Washington, D.C., and he created this notion of “jumping Jim Crow” as a way to entertain predominately white working-class audiences.

Popular entertainers would perform as black caricatures, with makeup that included the application of burnt
cork to the face. They would “act black” by reproducing every stereotype known to the white audiences of the time. “Zip Coon,” “Tambo,” “Sambo,” “Jim Crow,” and “Jim Dandy” all corresponded with white stereotypes of black men. In addition, black women were often subjected to the same level of ridicule in the caricatures of “Mammy,” “Jezebel,” and “Sapphire.” Before the Civil War, these stereotypes were often used to justify slavery, for they were meant to show the supposedly inferior essential characteristics of slave men and women. This Sambo stereotype was clearly at work in Bishop Whipple’s Southern Diary, 1834–1844. The author, an Episcopal clergyman named Henry Benjamin Whipple, wrote of the slaves he encountered on a trip through the South: “They seem a happy race of beings and if you did not know it you would never imagine they were slaves. The loud laugh, the clear dancing eye, the cheerful face show that in this sad world of sin and sorrow they know but very few.”

In the separate but unequal period of black-white relations (1865–1964), segregated institutions often found their legitimation in the stereotypical representations of blacks “knowing their place.” The minstrel characters included the uppity Zip Coon, who becomes the buffoon because he wrongly thinks he’s successful, and the happy, ignorant, subservient Jim Crow and Tambo, who sing and dance their troubles away. At the tail end of the Jim Crow era, Edward R. Murrow aired his famous “Harvest of Shame” broadcast on Thanksgiving evening 1960. Murrow detailed the horrific working and living conditions of white and black migrant farmworkers. A Florida grower in the exposé had this to say about African American workers on his farm: “They love to go from place to place. They don’t have a worry in the world. They’re happier than we are. Today they eat, tomorrow, they don’t worry about [sic]. They are the happiest race of people on earth.”

POPULAR CULTURE AND BLACKFACE PERFORMANCES

What cannot be overstated is that minstrel shows embodied the first form of popular culture in the United States. There is a direct line from minstrels to vaudeville, Broadway shows, motion pictures, radio, and television. Ziegfeld Follies, Christy’s Minstrels, the lyrics and performances of Stephen Foster, and Al Jolson’s The Jazz Singer mark the most popular performances of antiblack racism in the Jim Crow era. Rather than being an aberration, performing in blackface and invoking racist stereotypes was a mainstay of Hollywood motion pictures. White actors who performed in blackface included Shirley Temple, Al Jolson, Bing Crosby, Eddie Cantor, Bob Hope, Fred Astaire, Judy Garland, Mickey Rooney, and even Mickey Mouse.

Radio and Television One of the most popular radio programs of the pre-television era was Amos and Andy, which was performed by two white actors. The show simply took the 1808 Sambo and Toney dialogue and updated it to the times. Many of the first television programs were based on the most popular radio programs of the day. Given the longstanding radio success of Amos and Andy, it was no surprise that a television program would be in the works. But two white men performing in blackface did not seem as apropos for the new medium, particularly given the vocal opposition of the NAACP to stereotypical blackface representations. Therefore, the CBS network hired the first all-African American acting crew to re-create the program. But the content of the television show did not veer from the original radio program and the black actors were expected to perform the stereotypes of Sambo, Jezebel, Sapphire, and Zip Coon.

Another early popular television program, Stepin Fetchit, took the Sambo stereotype to a similar level. The black actors Bert Williams and Lincoln Perry were both of Afro-Caribbean parentage and did not grow up in the United States. Thus, they were not similarly situated in their upbringing to see how the African American stereotypes of the stupid and docile buffoons they were playing reinforced inferior social conditions for black Americans.

Buffoonery was the main representation of blacks on television. With the advent of children’s cartoons, the common tropes deployed in blackface comedies were in evidence. While Our Gang and the Little Rascals were best known for redeploying the racist caricature of black children as pickaninnies in the characters of Stymie and Buckwheat, the inevitable cartoon explosions, with the resultant blackface or pickaninny image, was frequently used in Warner Brothers, Disney, MGM, Hanna-Barbera, and most other children’s cartoons.

Children’s Books Children were long subjected to the Sambo stereotype in early picture books and later comic books. The Story of Little Black Sambo is the most famous of these products. Written by Helen Bannerman in 1899, the story is a combination of the Sambo and uppity Zip Coon stereotypes though it is set in India, with tigers and allusions to Hindu culture. The story tells of a happy-go-lucky black child who loses his fancy clothes to tigers. It is built on a well-entrenched and blatantly racist structure of storytelling. Over time, the illustrations in various editions of the book increasingly took on the blackface motif for the story’s protagonist and his parents (Black Mumbo and Black Jumbo). Updated versions placed the story on a plantation in the U.S. South.

Sambo’s Restaurant The Story of Little Black Sambo found yet another life when a restaurant chain began to use the
images of the book, and the story itself, to encourage children to eat there. The restaurant, named Sambo’s, was officially not named to invoke particular stereotypes. The owners, Sam Battistone and Newell “Bo” Bohnett, expressly identified their own names as the basis for the restaurant name, but they quickly incorporated the Little Black Sambo motif into the menu, placemats, advertisements, and promotions.

The Sambo’s chain was purchased by the Denny’s chain of restaurants in 1984, and for a time the two restaurants coincided with the same signage but distinct names. After social protest and continued pressure from African American organizations, the Sambo’s chain ceased to exist. But the more insidious nature of racism would rear its ugly head in the Denny’s corporation when, in the 1990s, it faced class action lawsuits by African American customers, who successfully argued that Denny’s was guilty of discriminatory practices and routinely not serving blacks.

Denny’s and Sambo’s were ubiquitously identified by the black community as particularly hostile to black customers, and a series of well-publicized events, occurring across the country, cemented a sense that an informal policy was in place to require its black patrons, and only its black patrons, to prepay for meals. As a result of the branding of Denny’s as a racist company, the corporation underwent a major makeover that involved legally required actions and a massive public relations campaign designed to increase the number of minority-owned franchises. Mandatory racial sensitivity training was undertaken, and an explicit nondiscrimination policy, based on a U.S. Department of Justice–enforced consent decree, was established. The claim that stereotypical images are harmless was severely undercut when it became clear that a chain restaurant long steeped in those stereotypes also perpetrated the most grievous practices of discriminatory treatment against the victims of the stereotypes.

SAMBO IN ACADEME
The Sambo stereotype was a staple of popular culture, but academic research was not immune from stereotypical reasoning. Stanley Elkins’s 1959 analysis of slavery as a total institution can be credited for sparking the new social history of slavery research. Historians such as Eric Foner, Herbert Gutman, and Eugene Genovese wrote some of the most widely acknowledged analyses of slavery in part to discredit the claims of Elkins. The dubious hypothesis that Elkins sought to verify was that the peculiar system of U.S. chattel slavery caused the Sambo social psychology of slaves: “Sambo, the typical plantation slave, was docile but irresponsible, loyal but lazy, humble but chronically given to lying and stealing; his behavior was full of infantile silliness and his talk inflated with childish exaggeration” (Elkins 1959, p. 87).

Elkins never empirically verifies that Sambos existed, but he assumes their presence. The following generation of historians effectively challenged this assumption with a body of research that found U.S. slaves to be much more contentious, to be purposive as actors fighting against slavery, and to have great strength in maintaining family and cultural ties in spite of oppressive social conditions.

In popular culture, a series of challenges to the Sambo stereotype have also surfaced. In particular, the Spike Lee movie *Bambooziled* (2000) tells the story of an African American television executive, Pierre Delacroix, who creates the impromptu idea for a new millennium minstrel show in order to save his job. To his chagrin, the white executives love the idea, and Lee effectively demonstrates the damage inflicted on the black actors selected to perform in blackface, as well as the larger societal damage inflicted on everybody involved in the production and consumption of racist stereotypes. In the closing scene, when Delacroix finally comes to terms with the monster he has created, he is seen in his office, which is filled with racist memorabilia. A Sambo coin bank takes on a life of its own until Delacroix eventually destroys it, along with all the lawn jockeys, blackface knick-knacks, and Mammy cookie jars.

As much as this movie was intended to put executives and white audiences on the spot for the perpetuation of stereotypes, it is clear that the message has not been fully received. In *Star Wars Episode I: The Phantom Menace* (1999), a character named Jar Jar Binks was introduced, and though his form is frog-inspired, his mode of speech and general demeanor is Sambo-inspired. The continuing struggle for African American actors is to find roles that allow them to play more than the fool. Most of the television shows featuring African American casts are comedic in genre, and they invariably have one or more characters playing the hapless fool. A strong case could be made that the history of being white in America corresponds with a strong fascination with all things black, except for black people. It is within this context that blackface minstrels, television comedies, Eminem, Elvis Presley, and contemporary jazz and blues bars make sense.

Sample Attrition

Sample attrition is a feature of longitudinal or panel data in which individual observations drop out from the study over time. Attrition may occur for a number of reasons, including insufficient compensation for survey response, induction into military services, transfer of residence with no follow-up information, or death of the respondent.

A dataset suffering from attrition is referred to as an attrited sample, whereas individual observations that drop out over the course of the panel are referred to as attriters. Assuming a longitudinal dataset is randomized at the inception of the data collection process, sample attrition would not pose any challenges in estimation of the attrited panel data if sample attrition occurs randomly. This would be the case if the attriters compose a random selection of individuals in the survey, and the underlying causes of attrition are independent of the survey response being studied. However, attrition in actual panel data is rarely random, since the probability of attrition is most often dependent on the observable and unobservable attributes of the individual observations that simultaneously affect the response variable being studied. For example, in firm-level data used to study business firm profits over time, firms could make a decision about whether to shut down (and thus, be removed from the sample) based on observable characteristics, as well as unobservable firm characteristics such as expected operating revenues and productivity, which are either directly or indirectly a determinant of firm profits as well. Thus less productive firms attrite from the sample, leaving a nonrandom sample for analysis. Any quantitative inference about the entire population of firms based on analysis of just the attrited sample would thus be misleading, since the attrited sample is nonrepresentative of the underlying population. In these cases, estimation of the panel dataset while ignoring sample attrition would lead to biased and inconsistent estimation, and thus incorrect inference.

Sample attrition was first formally described and analyzed in J. Hausman and D. Wise’s work *Econometrica* (1979). Using the well-known random-effects specification, Hausman and Wise considered models in which the unobservable errors that determine the attrition decision are naturally correlated with the unobservable errors that determine the response variable. Due to this choice of specification, this model is sometimes referred to as the Selection on Unobservables model. The specification is easily manipulated to illustrate that least squares regression using only the retained data would be biased and inconsistent for the parameters of interest. The model also shows that using only the first period randomized sample leads to biased and inconsistent estimators, if future periods are affected by attrition. The latter is a consequence of the unavoidable correlation of error terms due to latent individual specific effects that do not change over time.

Then, under the joint normality assumption on the errors, it is shown, however, that consistent estimators of the parameters of interest can be obtained by the maximum likelihood (ML) procedure. Generalizations, including models with relaxed distributional assumptions, have been suggested by various researchers, including M. Verbeek and T. Nijman in the *International Economic Review* (1992) and Jeffrey Wooldridge in the *Journal of Econometrics* (1995). Cheng Hsiao provides a review in his *Analysis of Panel Data* (1986).

Several late-twentieth-century theoretical advances have been suggested in the analysis of sample attrition models. These have included models wherein an observable determinant of sample attrition is uncorrelated with the response variable, but possibly correlated with the unobservable determinant of the response variable. This difference from the original attrition model has led to this model being known as Selection on Observables, as studied in John Fitzgerald, Peter Gottschalk, and Robert Moffitt’s 1996 research. This model is complementary to the classical attrition model studied by Hausman and Wise; each is formulated on a different assumption and each is of independent interest in empirical research.

A separate consideration in the theoretical work on sample attrition has been the possibility of obtaining a refreshment sample, which refers to supplemental data randomly sampled from the population to augment the attrited sample. This type of approach has been considered by, among others, K. Hirano and colleagues in 2000, who proposed consistent estimators of the parameters of interest when such refreshment samples are available.
Sampling

In 2004, Mitali Das considered a generalized model of attrition. This model permits the estimand of interest to be either a parameter (as in previous work) or a flexible and unknown function, permits the errors to have unspecified joint distribution, and usefully permits attriters to reappear in future periods.

SAMPLING

A sample is a subset of items, objects, or elements from a larger group of interest, called the population. When an observed sample is used to make inferences about the unobserved population, chance factors must be considered and the risk of being wrong must be assessed. Statistical sampling uses probability to measure this uncertainty. Statistical, or probability, sampling implies that every item or subset of items in the population has a mathematically determined likelihood of being selected; which item or items in the population will be selected is left to chance and not to judgment. A sample consisting of numerical values that have meaning on a number line (for example, numbers on a ruler) is assumed to have been generated by a random variable that has a specific probability distribution.

SIMPLE RANDOM SAMPLING

In simple random sampling, each item in the population is equally likely to be selected. For instance, if the population of interest consists of \( N \) elements, then each and every possible sample of \( n \) elements (where \( n \) may equal 1, 2, 3, \( \ldots, N-1 \)) should have a probability of \( 1/N^n \) of being realized. (Typically, in textbooks, upper case \( N \) is used to denote the number of elements in the population, and lower case \( n \) gives the number of elements in the sample.) An example would be to blindly draw well-shaken numbered slips of paper from a hat or drum one at a time, with each slip placed back in the hat. Replacement ensures that each number is equally likely on each draw, although computerized random number generators are typically used to simulate it.

In drawing numbers from a hat or in a laboratory experiment, replacement might seem possible; in actual business and economics practices, however, replacement is seldom possible. If the population of interest is extremely large relative to the sample size, then even though the probability of each sample being selected in repeated sampling does not remain fixed, the changes in probability could be trivial. For instance, if \( n = 30 \) and \( N = 30,000 \), then for the first sample the probability of drawing 30 items is

\[
\frac{n!}{(N-n)!} = \frac{30!}{(30-30)!} = \frac{30!}{30!} = 1
\]

On the second sampling, it is

\[
\frac{n!}{(N-2n)!} = \frac{30!}{(30-2*30)!} = \frac{30!}{30!} = (10)^{-88}
\]

As long as \( N \) is large relative to \( n \), whether there is or is not replacement will not be critical. In practice, randomization based on the notion of fixed sampling probabilities is more a matter of degree than an absolute.

Putting numbered items in a hat to be shaken or into a revolving drum, may give the appearance of good mixing, but the resulting selections will not necessarily produce a sample that represents the population. For instance, in 1970, during the Vietnam War, military draft status for induction into the U.S. Armed Forces was determined by the order in which birthdays were drawn from a drum. The Selective Service placed 366 capsules in a drum, each representing a birthday. The drum was turned several times and capsules were selected “at random.” As Norton Starr discusses in detail, this method looked impressive on television, but the results were not a good representation of birthdays. Randomization suggests that among the first 183 birthdays selected, about one-sixth should be from November and December. Of the first 183 days selected, however, 46 were from November and December, well above the expected 30 or 31. This led to speculation that more than simple random sampling error was involved.

SYSTEMATIC SAMPLING

Systematic random sampling involves the selection of every \( k \)-th element (or block of elements) from a list of elements, starting with any randomly selected element. Systematic sampling is a popular way of generating samples in accounting and quality-control work. It is typically less expensive to select every \( k \)-th element than to search for the \( n \) randomly determined items. In systematic sam-
pling, however, only the first of \( n \) items can be considered as randomly determined.

Systematic sampling is convenient for populations formed by lists, stacks, or series. For instance, if students with e-mail addresses at a university is the population of interest, systematic sampling could be used to minimize the likelihood that those with the same last name (who may be relatives) would be included in a sample. However, if the data have cyclical components, then systematic sampling may be inappropriate.

**STRATIFIED SAMPLING**

When the population is known to consist of a number of distinct categories, characteristics, or demographics, the sampling process can be made more efficient (requiring a lower sample size for the same precision) if the population is divided into subgroups that have the common attribute. For example, in a study of starting salaries, recent university graduates might be grouped, or “stratified,” by their majors. In a study of higher-education costs, universities might be placed in one of two subgroups: public or private. Heterogeneous populations can always be divided into subgroups that are more homogeneous if those in the population can be identified by the characteristic. These more homogeneous subgroups are called “strata.” Either simple random sampling within strata or one of a number of sampling methods is then applied to each stratum separately, where sample size for a strata is made proportional to the stratum’s share of the population.

**Cluster Sampling** If sampling requires face-to-face communication and the members of a population are physically separated from one another (as in different cities), then it would be very costly to visit randomly selected homes. Instead, sampling might be restricted to a few cities. Within these cities, a surveyor visits specific neighborhoods, interviewing an adult from every \( i \)-th house on \( j \)-th street. Such sampling is called cluster or area sampling because groups or clusters of elements are first selected and then elements within a cluster are chosen. At each stage, selection can be random or based on nonrandom judgment.

**Classical Statistics and Sample Statistics** Classical statistics assumes simple random sampling. Random “draws” imply that each sample of size \( n \) will yield somewhat different values. Thus, the value of any statistic calculated with sample data (for example, the sample mean) varies from sample to sample. A histogram (graph) of these values provides the sampling distribution of the statistic. Many Web sites show how the distribution of the sample means changes with \( n \). Robert Wolf, for example, has designed “Statutor,” a computer-based tutorial on sampling distributions, estimators, and related topics that can be freely downloaded.

The law of large numbers holds that as \( n \) increases, a statistic such as the sample mean (\( \bar{X} \)) converges to its true mean (\( \mu \)). That is, the sampling distribution of the mean collapses on or degenerates to a spike at the population mean. The central limit theorem, on the other hand, states that for many samples of like and sufficiently large size \( n \), the histogram of their sample means will appear to be a normal bell-shaped distribution. As the sample size \( n \) is increased, the distribution of the sample mean at first becomes normal (central limit theorem) but then degenerates to the population mean (law of large numbers). Only the standardized mean, \( (\bar{X} - \mu)/\sqrt{n}/\sigma \), maintains its shape as \( n \) goes to infinity, where \( \sigma \) is the population standard deviation.

**Sampling and Inferential Statistics in the Social Sciences** Unlike laboratory random experiments, sample data in the social sciences are often “opportunistic,” meaning they have been observed with no explicit and certain knowledge as to how they were generated. In such cases, the researcher must have a theory about the data-generating process. For example, one might assume that observation \( i \) at time \( t \) on dependent variable \( Y_{it} \) was generated by \( k \) independent variables, \( X_{1t}, X_{2t}, X_{3t}, \ldots, X_{kt} \), plus an error term \( \varepsilon_{it} \) reflecting random chance factors, where the betas are parameters to be estimated:

\[
Y_{it} = \beta_0 + \beta_1 X_{1t} + \beta_2 X_{2t} + \ldots + \beta_k X_{kt} + \varepsilon_{it}
\]

A maximum likelihood estimator of the betas requires the researcher to make an assumption about the error term (for example, \( \varepsilon_{it} \) is normal with mean zero and unit standard deviation) and then have a computer program search for values of the betas that maximize the probability of getting the observed sample values of the \( X \)s and \( Y \). Here the sample \( Y \) values are assumed to come from this model, conditional on the values of the \( X \)s, with the randomness in \( Y \) generated by the assumed distribution of the epsilon error term. If the assumed population model of the data-generating process is wrong, then the estimated parameters are meaningless. Unlike data obtained from simple random sampling in a laboratory experiment, opportunistic sample data cannot be used to make inferences without a theory about the nature of the data-generating process.

SAMUELSON, PAUL A.
1915–
If one could do a mental time-and-motion study of a modern economic theorist at work, a large fraction of what he or she actually does from day to day would turn out to have its origins in Paul Samuelson's work. In that precise sense, Samuelson has been the economist's economist.

Paul Anthony Samuelson was born in Gary, Indiana, on May 15, 1915. He graduated from Hyde Park High School in Chicago in 1932 and went on to the University of Chicago and an already precocious B.A. in 1935. The next step proved to be important: he moved to Harvard for his Ph.D., studying with Joseph Schumpeter (1883–1950), Gottfried Haberler (1900–1995), Wassily Leontief (1906–1999), and, more to the point, the polymath Edwin Bidwell Wilson (1879–1964), from whom he may have learned some tricks of the trade in dealing with equilibrium systems of equations. From 1937 to 1940 Samuelson was a junior fellow of the Harvard Society of Fellows; that was—and is—a plum appointment, providing a stipend, stimulating company, and three undisturbed years in which to pursue one's own research. In 1940 he was appointed assistant professor of economics at Massachusetts Institute of Technology (MIT), retiring as institute professor emeritus in 1986. If Harvard had retained Samuelson as an assistant professor, the history of economic thought might not have been affected, but the center of gravity of economic teaching would not have shifted so strongly toward MIT. Anti-Semitism certainly played a significant role in Harvard's failure to keep him, but there were other factors as well: Lloyd Metzler and James Tobin also slipped away.

Samuelson has probably been the last great generalist in economics. His five volumes of published papers (with more in the works) range from the pure theory of consumer demand to macroeconomics and the history of economic thought. The place to start, however, is with The Foundations of Economic Analysis, published in 1947 (and reprinted with additions in 1983) but already containing the results of earlier articles. It is fair to say that this book was the major influence in the transformation of economics into the mathematical-model-building discipline it is today.

Of course there had been many important prior uses of mathematics in economic theory. What the Foundations did was to turn scattered stand-alone efforts into a paradigm, in Thomas Kuhn's (1922–1996) original sense of a standard way to answer standard questions. In particular, Samuelson explained, exemplified, and inculcated the notion of comparative statics, aimed at answering a fundamental class of questions: how do the coordinates of an equilibrium point defined by a system of equations shift when one or more of the given determining parameters changes? Bread-and-butter examples range from determining the effects of a changing excise tax on the price and quantity of a single good to determining the effect of a changing quantity of base money on the basic variables of a macroeconomic model. A second focus of the book was on the logic of constrained maximization, and a third on the importance of explicit dynamic modeling both for its own results and for understanding the stability, and therefore the significance, of a longer-run equilibrium. The wealth of examples was an eye-opener to younger economists.

Despite the broad landscape over which his work has ranged, there are especially important concentrations. His first three articles, dating from 1937 to 1938, are on utility theory and consumer behavior, the pure theory of capital, and welfare economics and international trade. The theory of consumer behavior has been on Samuelson's mind for seventy years.

There is a story that, asked by a science department colleague at MIT to name a theory in economics that was neither false nor trivial, Samuelson named the theory of comparative advantage. True to his word, he has made outstanding contributions to the theory of international trade. They include a complete statement and clarification of the gains from trade, the factor-price equalization theorem (when does free trade in produced goods induce uniform prices of immobile factors, wherever they are, and when does it not), the transfer problem, and more.

Yet another such monument is the theory of public goods (initiated by Erik Lindahl [1891–1960] but worked out in its modern form by Samuelson). These are goods the use of which by one “consumer” does not foreclose use by others. Examples include weather forecasts, national defense, and clean air. Instances with a “public-good element” outnumber the pure public goods, and this adds importance to the problem.

There is room merely to mention only one more of these clusters in Samuelson's work, the theory of finance. Here he has not only made contributions himself—for example, the martingale property of asset prices, and even
the beginning of a theory of option pricing—but he has directly inspired the work of others. For further references, comments by specialists, and discussion of Samuelson's contributions to still other branches of economics, see E. Cary Brown and Robert M. Solow (1983) and Michael Szenberg et al. (2006).

What has been described so far was aimed at other economists. Another side of Samuelson's activity has been directed at a broader public. Apart from columns in newspapers and magazines in the United States and elsewhere and many public lectures, there is the famous elementary textbook *Economics*. The first edition was published in 1948, with up-to-date revisions published at approximately three-year intervals until 1985, when it acquired the joint authorship of William D. Nordhaus of Yale. Successive editions have followed, the 2005 edition being the eighteenth. For many years *Economics* was the runaway leader in sales, but it was eventually overtaken by other textbooks, most of which had imitated the form and tone that Samuelson had pioneered.

*Economics* was an innovator in several respects. The textbook taught economics to beginning students as the model-building enterprise it had become, taught to them in simplified form, of course. Students were expected to use the supply-and-demand apparatus or a simple macroeconomic model as devices for understanding made-up events, and also real-world data. It was a style of teaching that lent itself to problem sets, certainly appropriate at MIT but equally appropriate to the view of economics as a pragmatic discipline, a “How Things Work” discipline. The three-year revisions were intended to keep the noses of students, classroom teachers, and the author to the grindstone of what was actually happening in the economy at large. The unity of theory and practice has been a hallmark of Samuelson’s work.

**SANDINISTAS**

The Sandinista Front for National Liberation (FSLN) is a Nicaraguan political party. It was formed to oppose the Somoza family dynastic dictatorship, which ruled from 1936 to 1979. It is named after Augusto Cesar Sandino (1893–1934), a Nicaraguan nationalist and anti-imperialist patriot who fought a seven-year war from 1926 to 1933 against a U.S. occupation force. On February 21, 1934, after putting down his weapons, Sandino was killed at the order of Anastacio Somoza Garcia, the head of the U.S.-formed Nicaraguan National Guard. In 1936 Somoza Garcia consolidated his political power, overthrowing the civilian government and staging a rigged election to install himself as president. He was inaugurated on January 1, 1937. From then until 1979 either he, one of his two sons (Luis and Anastacio Jr.), or—for brief periods—one of their cronies ruled Nicaragua.

The FSLN was originally formed clandestinely in 1961. The organization’s founding members included Carlos Fonseca, Silvio Mayorga, and Tomas Borge. Particularly important to the organization’s formation and early development, Fonseca is widely credited as the organization’s intellectual father. His revolutionary ideology came to be known as *Sandinismo*—which combines elements of Marxist class analysis and Sandino’s own nationalist and anti-imperialist ideology as applied to the Nicaraguan social, political, and economic reality. This led the Sandinistas to organize for the military overthrow of the Somozas because they were convinced that the Somozas were completely unresponsive to peaceful demands for democratization and economic reform.

Throughout the 1960s and early 1970s the Sandinistas suffered serious setbacks, including the death in combat of all of its original founders, except Borge. These losses led to a regrouping period in which they sought to accumulate strength in secret while organizing politically. However, it also led to a split into several competing Sandinista factions. The first, called the Extended Popular War (Spanish acronym GPP) Tendency, advocated building grassroots peasant support in the countryside. In contrast, the Proletarian Tendency grew out of the urban underground and advocated the organization of union workers into self-defense units. The final faction, called the Terceristas (Third Way), favored a more pragmatic approach combining different forms of struggle and advocated the creation of a broad alliance of all Nicaraguans opposed to Somoza to generate a national insurrection.

**THE REVOLUTION**

By late 1978 the long awaited national insurrection began and many of Somoza’s supporters abandoned him. To take advantage of this opportunity the Sandinistas reunited
early in 1979 and created a single nine member National Directorate with three representatives from each faction. The members were Daniel Ortega, Humberto Ortega, and Víctor Tоро (Terceristas); Tomás Borge, Bayardo Arce, and Henry Ruiz (GPP); and Jaime Wheelock, Luis Carrión, and Carlos Nuñez (Proletarian faction). On July 19, 1979, the Sandinista Revolution triumphed, ousting Anastacio Somoza Jr.’s regime in a mass popular insurrection.

Once in power the Sandinistas embarked upon ambitious political and economic programs designed to democratize Nicaragua and lift the country out of underdevelopment. Their political agenda called for reforming the country’s institutions, including disbanding Somoza’s National Guard, and enfranchising the country’s vast rural and urban poor through mass organizations affiliated with the FSLN. In 1984 they carried out the first democratic national elections in the country’s history, which the Sandinistas won with 66 percent of the vote. Though derided by U.S. president Ronald Reagan’s administration as a “Soviet style farce,” the elections were designed with the technical assistance of the Swedish Electoral Commission and observed by credible international organizations and European governments. The newly elected Constituent Assembly, with the help of open “town meetings” around the country, promulgated a new constitution in 1987. Simultaneously, the Sandinistas launched aggressive economic reforms to combat the twin evils that had historically plagued Nicaragua: poverty and inequality. To this end they implemented an agrarian reform to distribute land confiscated from Somoza and his cronies (one-fifth of the country’s arable land) to individual peasants, cooperatives, and collective farms. In the cities they passed popular economic reforms, such as raising the minimum wage and introducing price controls and subsidies on basic goods and services, and embarked on public works programs to increase employment. These coincided with the Sandinistas’ desire to implement a mixed-economy in which private property, state property, and cooperative property would co-exist. Sandinista social policy was equally ambitious, especially in the areas of education, health care, and housing.

From 1979 until Ronald Reagan’s inauguration in 1981, U.S.–Nicaraguan relations were cool but nonconfrontational. However, shortly after entering office President Reagan signed a secret executive authorization to begin trying to overthrow the Sandinista government, which the United States accused of supporting the guerrillas in El Salvador, being too closely allied to Cuba, and being Communists. U.S. coercion ranged from diplomatic pressures and economic sanctions to supporting the rebel force known as the Contras and threatening direct U.S. military action. These policies put a huge economic strain on the Nicaraguan economy, and the Sandinistas were forced to respond by shifting much of their trade to Europe and the Soviet Union. Similarly since the early 1980s, sales of weapons from Western countries were also embargoed pushing the Nicaraguans to import most of their weapons from the Socialist Bloc. While the Sandinistas claimed that these weapons were for defensive purposes to fight the U.S.-supported Contra rebels, the Reagan Administration pointed to them as proof that the FSLN were Communists and presented an eminent threat to other countries in the region and ultimately the United States. However U.S. public support for military intervention, whether indirectly by supporting the Contras or directly by U.S. troops, was the most unpopular U.S. foreign military policy of the 1980s. Indeed widespread domestic opposition led to strong public pressure on Congress to limit aid to the Contras. It also eventually led to the outlawing of lethal aid for the Contras from 1984 to 1985.

In turn this led members of the Reagan Administration, notably Oliver North of the National Security Council, to engage in the illegal and covert funding of the Contras by giving them money received from selling arms to a hostile country, Iran, in exchange for the release of U.S. hostages held by Lebanese Hezbollah. When this back-channel funding was uncovered it became known as the “Iran-Contra scandal.” An independent counsel, Lawrence E. Walsh, was appointed to investigate the affair. Eventually several members of the Reagan Administration were prosecuted and convicted. However, these convictions were later overturned on appeal or through presidential pardons.

From 1984 through early 2007 the electoral system that the Sandinistas put in place peacefully transferred power four times. The first was in 1990 when the Sandinistas were voted out of office. For the next sixteen years, three conservative administrations held power. However, on November 5, 2006, Sandinista candidate Daniel Ortega was reelected president of Nicaragua on a social democratic platform. The 2006 elections were widely scrutinized by international observers including delegations from Europe, the Organization of American States, and the Carter Center in Atlanta, Georgia. By all accounts they were, with the exception of a few minor irregularities, fair and transparent. In January 2007 Ortega began his new term in office.

SANITATION

*Sanitation* (from the Latin *sanitas*, meaning health) refers to the maintenance and delivery of clean, hygienic conditions that help prevent disease through services such as drinking water supply, garbage collection, and safe disposal of human waste. Sanitation is the focal point of public health policy, but in the experience of local communities much more than health is at stake in “sanitation.”

GLOBAL STATISTICS

World Health Organization (WHO) reports show that in 2004, 5.3 billion people (83% of the world population) had access to clean water sources (in 1990 that percentage was 78). Of the 1.1 billion people without access to clean drinking water, 84 percent live in rural areas. The situation is particularly critical in sub-Saharan Africa, where 44 percent of the population remains without clean drinking water, and in Eastern and Southern Asia.

Similar statistics apply to the coverage of “basic sanitation” (improved toilet facilities). According to the same 2004 WHO report, only 59 percent of the world population had access to a hygienic toilet in 2004. It is again sub-Saharan Africa (38 percent) and Eastern Asia (45 percent) that have the highest populations without basic sanitation.

Unsanitary conditions are the main cause of ill health and premature death in poor societies. WHO statistics of 2004 report that 1.8 million people die every year from diarrheal diseases (including cholera), 90 percent of whom are children under five. Eighty-eight percent of diarrheal disease is attributed to poor sanitation. Malaria, another sanitation related disease, kills 1.3 million people each year; again, 90 percent of these deaths are children under five. Other diseases that originate in poor sanitary conditions include schistosomiasis (a parasitic infection), intestinal helminthes (ascariasis, trichuriasis, hookworm), and hepatitis-A. Although the health consequences of sanitation are overwhelming, people often have reasons to pursue—or refuse—better sanitation.

EVOLUTIONIST VIEWS: SURVIVAL INSTINCT

Social scientists have developed various theories to interpret or explain human concern about avoiding dirt and promoting hygiene. Evolutionist thinkers believe that there is medical wisdom in the human fear of dirty things. Dirty objects and activities pose a danger, so it is wise to avoid them. Disgust of dirt is a survival strategy (usually a non-conscious one). A 2001 study by Valerie Curtis and Adam Biran list five disgust elicitors derived from research in India, Burkina Faso, The Netherlands, Britain, and an international airport. The five elicitors are: (1) body excretions and body parts; (2) certain animals; (3) decay and spoiled food; (4) certain categories of “other people;” and (5) violations of morality. Bodily excretions were mentioned most frequently as causing disgust and among them, feces topped the list, but vomit, sweat, spit, blood, pus, and sexual fluids were also regarded with aversion. Animals that were mentioned most often included pigs, dogs, rats, snakes, worms, cockroaches, maggots, lice, and flies. People that were found disgusting were those with signs of sickness, dirt, or deformity, and strangers with whom one was forced to come into close contact, for example in crowded places. People who behaved immorally also evoked aversion.

Curtis and Biran’s hypothesis is that humans have evolved behavioral defenses against disease and that “disgust is one of the mechanisms crafted by natural selection to keep our distance from contagion” (Curtis and Biran 2001, p. 22). The researchers found support for their hypothesis by checking the routes of transmission for a selection of common infectious diseases. In all of them, one or more elicitors of disgust were mentioned as playing an important role in transmission. Feces were named as the source of more than twenty infectious diseases. Breath, saliva, lice, rats, and sexual organs were also important sources or transmitters of infection. All of these score high for human disgust.

William Ian Miller’s 1997 study of disgust is difficult to place in any disciplinary tradition. His own expertise mainly lies in literature and history but his study also draws on psychologists, moral philosophers, and political and social theorists. Trying to decipher the origin and working of emotion, Miller derives most inspiration from psychology.
Sanitation

The disgust Miller discusses applies to many phenomena and activities, such as defecation, sex, food, and drink. He distinguishes two types of disgust. The first, which is clearly Freudian, prevents the activation of unconscious desire. It defends against pollution, denies access to objects and acts that would block the psychic development of the human person. The evolutionist perspective of disgust as a survival instinct returns here at the level of the human psyche. The second type of disgust is “disgust of surfeit,” it punishes after having indulged in a “disgusting” activity. The two types complement each other. In the aversion of things perceived as dangerous because of their power “to contaminate, infect, or pollute by proximity, contact, or ingestion” it is first of all the unconscious reaction to psychic dangers that is at work (Miller 1997, p. 2).

CIVILIZATION PROCESS
Most authors writing on hygiene and sanitation from a sociological point of view refer to Norbert Elias’s study on the civilization process. Elias studied etiquette books, letters, and other documents in France and England from the eleventh century onward and describes how the authors of those guides for proper conduct gradually became more particular about body functions, body parts, and body products.

He talks about a general process of civilization, which implies a “privatization” or “intimization” of human behavior. More and more, public activities became shameful and were confined to the private world. The human body was a focal point. The body itself had to be well covered and activities such as sex, sleep, urination, and defecation became embarrassing when carried out in front of other people. Modern hygiene facilities are regarded as expressions of the civilizing process.

CULTURAL SYMBOLS AND RELATIONAL CONCERNS
The symbolic anthropologist Mary Douglas, in her classic Parity and Danger, turns away from evolutionist and “medical materialist” (a term used by American psychologist and philosopher William James, meaning reducing ritual to its supposed positive medical effect) explanations of hygiene and presents dirt as “matter out of place,” a definition that became famous for its beautiful simplicity and provocation. Shoes on the table (Douglas’s example) are dirty; under the table they are clean. Saliva safely caught in a handkerchief is hygienic, but when it falls in a plate it turns disgusting. Her claim that absolute dirt does not exist opened new windows in the study of hygiene as a cultural phenomenon. Dirt is defined by its context. It is disorder and carries an invitation or rather an obligation to restore order: “Ideas about separating, purifying, demarcating and punishing transgressions have as their main function to impose system on an inherently untidy experience” (Douglas 1970, p. 15). Hygiene, in short, is a basic cultural act: it distinguishes dirt from what is clean and thus, creates cultural order. Enculturation of small children starts with teaching them what is clean and what is not clean. Hygiene is the essence of culture. What is dirty is of less importance. Crucial is that dirt exists. Without the concept of dirt people could not formulate the norms and values of culture.

RELATIONAL CONCERNS

What makes an object abject and threatening? Douglas suggested: its out-of-place condition. Others claimed it depends on the matter itself. Too little attention has, however, been given to the identity of the person who is directly associated with something dirty, to the social life of the dirty matter. The answer to the question “whose?” determines the experience of disgust much more than has been suggested by Douglas and other authors who wrote about the cultural meaning of dirt. By adding a sociological dimension to dirt, Douglas’s theory of matter out of place becomes more true to life and effective as an interpretative tool.

The humanist Erasmus’s dictum that one’s own shit has a pleasant smell (Suus cinque crepitus bene olet) is a humorous exaggeration, but it is not exaggerating to say that people usually are not disturbed by the smell (and sight) of their own feces. Objects, substances, and acts become dirtier as the person behind them is less close or less liked. Animals that produce dirt are also placed in categories of less and more disturbing. Animals that are “part of the family” are experienced as cleaner than those who belong to another family. And so on. Acts and gestures from a loved person that are cherished as dear and intimate (bodily contact, sex) turn into horrifying violence when another person performs them. Good or bad, clean or dirty, in this case, depends entirely on the actor. The “matter” remains the same. The urge for “hygienic action” also depends a great deal on such relational concerns. Washing hands after toilet use or before eating, for example, is as much a social as a healthful act.

SANITATION POLICY
Hygiene, in the medical sense, is a core value in modern societies. Objects, activities, and people are judged by their medical qualities. Food, houses, streets, markets, working places, holiday camps, public transport, and visitors should be clean and not pose a danger to health. Dirty things and people are rejected and rejected things and people are called dirty.

Anthropologists and historians argue, however, that people do not always make that explicit link between
health and dirt. After studying the hygienic ideas and practices by mothers in Burkina Faso, Curtis concluded that their cleanliness and dirt avoidance were primarily a matter of “etiquette and social acceptability rather than to avoid illness” (Curtis 1998, p. 110). In a 2005 study, conducted in Bénin, Jenkins and Curtis observed that modern toilets were popular because they were seen as a sign of social prestige and success.

Michel Foucault argues that in the modern state, medicine is a major instrument of control by societal and political institutions. His concept of “Bio-power” suggests that the state can reward or punish its citizens by providing or withholding health. Sanitation, preventive health care, implies the imposition of a regime. Sanitary policy legitimates the state’s interference in households and private lives of people and thus helps to establish more effective disciplinary power. Bio-power—and sanitation in particular—constitutes the link between macro and micro (Foucault 1990; Gastaldo 1997).

Sanitation policies have been most successful when they also appealed to other values in people’s lives, such as social decency, respect, comfort, and religion. Cultural ignorance and lack of respect for local knowledge and practices of hygiene are major problems in sanitation projects by both foreign organizations and local governments in low-income societies. Tiokou Ndonko’s 1993 anthropological study in Cameroon for example, analyzed cultural and religious resistance against the government’s sanitation policy. Hygiene, seemingly a purely medical concern, lies at the heart of culture and is both a means of political control and resistance.

SANSKRITIZATION

The term Sanskritization was first coined by the Indian sociologist Mysore Narasimhachar Srinivas (1916–1999) in his Oxford University PhD thesis, which was eventually published as Religion and Society among the Coorgs of South India (1952). His research demonstrated that, contrary to the British colonial view, the caste system was not static and pan-Indian, but local, dynamic, and fluid. He captured the dynamics of this stratification system in his theory of Sanskritization. Sanskrit is the canonical language of the Hindu scriptures, including principally the Upanishads, and thus Sanskritization is the process by which lower castes attempt to emulate the culture of higher castes. More precisely, this social process involves the adoption by a “low” caste or other group of the customs, rituals, and beliefs of a “high” or “twice-born” caste. One specific example is the adoption of a vegetarian diet, which is not typical of low-caste practice. These social changes are normally followed by a claim to a more elevated position within the hierarchy of castes.

The theory is in fact more complex, because of the difficulties of translation of the notion of “caste,” which corresponds to what is locally known as jati or kulam. Whereas varna refers to the four main castes (Brahmin, Kshatriya, Vaisya, and Sudra), jati refers to the many smaller groups or subcastes by which the Indian system is internally and locally divided. A caste is characterized by endogamy, hereditary membership, and a specific lifestyle. Although social classes are open, caste in principle is not. Whereas social mobility in class society involves the movement of individuals, in a caste system it is an entire community (typically a jati) that moves up or down the system.

This social dynamic is also associated with a contrast between what anthropologists have called the “great” and
“little traditions” of peasant society. In his *Peasant Society and Culture* (1956) Robert Redfield argued that a “great tradition” is a culture closely associated with religion that is spread over a large territory and embedded in a literary tradition defended by a stratum of intellectuals such as priests. A “little tradition,” by contrast, is localized, limited, and oral. Little traditions can be absorbed into great traditions and become universalized, or there may be a reverse process whereby great traditions may become parochial. Sanskritization can be seen therefore as the process by which a local community immersed in the “little tradition” makes a claim for membership in the “great tradition” by acquiring elements of Sanskrit learning and ritual practice. The whole history of Hinduism can be interpreted as the constant interaction between the Brahmans (as priests and teachers) and the religious customs of other social groups.

The principal ambiguity of Srinivas’s theory is whether Sanskritization is a radical or conservative process. One can interpret the social mobility of *jati* as a social “safety valve” in which able and educated but low-status groups move up the hierarchy of caste to claim their place in society, thereby leaving the existing structure in place. Srinivas, however, saw the process as a progressive feature of a society that was becoming more open and democratic. Although Srinivas did not believe that the caste system would simply collapse under the pressure of modernization, he did argue that it would continue to adapt, especially under the impact of electoral politics at the village level. The increased provision of education, urbanization, and industrialization have had an impact on traditional relations between castes, but approximately one-seventh of the Indian population still bear the stigma of untouchability, despite affirmative action programs introduced by the Indian Constitution of November 26, 1949, rejecting untouchability as an infringement of fundamental rights. The Constitution’s principal legal architect was Bhimrao Ramji Ambedkar (1891–1956), who, although himself an untouchable, had been invited by the Congress-led government of newly independent India to serve as the nation’s first law minister. Ambedkar advocated the expansion of educational provision for the untouchables as an affirmative action program. These legal measures in the Constitution have been continuously reaffirmed in subsequent legislation such as the Untouchability (Offences) Act of 1955. However, given the resilience of untouchability in Indian society, it is evident that sanskritization is not a radical solution for social inequality.

**SANTERÍA**

Santería has long been called an Afro-Cuban religion: This designation highlights the origins of many of its elements and early founders but also obscures the fact that Santería has long been a major religion in Cuba practiced by diverse people and has become a global religious movement. Between 1780 and 1850 the Atlantic slave trade transported approximately 1 million enslaved people to Cuba. Nearly 500,000 came from West Africa, where they were in the process of forging the culture now called Yoruba. In Cuba they intermingled with others and forged a popular religion, related to but distinct from the traditional religion of the Yoruba.

**WORLDVIEW**

The world in which Santería’s followers live overflows with diverse kinds of spirits and divinities, and this “theodiversity” reflects and embodies the natural biodiversity of both tropical West Africa and Cuba. The supreme god, Olodumare, created the natural world in which humans now live as well as a host of *orishas* (divinities, called *orichas* in Cuban Spanish) responsible for its various aspects. Most orishas lived in heaven with Olodumare before descending to the earth. Here they revealed outrageous personalities, led phenomenal lives, and did memorable deeds, and then they ascended into heaven, turned into natural features (e.g., rivers), or disappeared into the earth itself. The stories and rituals for the orishas reveal their specific personalities, complete with foibles, virtues, and preferences for specific foods, objects, metals, and colors. Each orisha rules a specific part of nature and some
aspect of human life or society. Most people consider the orishas to be divine representatives or facets of Olodumare.

Elegguá, the mischievous messenger of the other orishas, wears red and black, carries a hooked stick for grabbing things, drinks rum, and smokes cigars. He lives in the forest, the savannah, bars, and crossroads. Always generous, Yemayá is the maternal ocean. A Great Mother figure, she dresses in blue and white, rules motherhood, and eats rams, ducks, pineapples, and watermelons. Obatalá, the father of the orishas, has clean white clothes and a cool, even character. He resides in high places, patiently forms human bodies and other creations, and eats white animals and fruits with white flesh. The sensual Oshún lives in the river and rules childbirth, dance, and erotic love. She loves brass, gold, pumpkins, oranges, and mangoes. Shangó is a fiery king invoked as the fourth ruler of the Yoruba city of Oyo. He wears red and white and makes his presence known through thunder and lightning. In Cuba approximately thirty orishas make up the pantheon, but people acknowledge the existence of an even greater number.

Each human being has a patron orisha and an innate spiritual component thought to reside within the physical head. Chosen by the individual before birth and authorized by Olodumare, this inner head (orinú) contains the individual’s destiny, character, and special talents, and it reflects the person’s essence (aché). The individual’s aché continues after death and becomes an ancestral spirit (egun), whom the living acknowledge and venerate through ritual.

Aché, the inherent essence and power to make things happen, exists in all natural objects and life forms. Certain herbs heal specific illnesses, and healing is their aché. A mixture of herbs sacred to the orishas helps consecrate priests and priestesses, and this is also called aché. Particular individuals have special talents that transform circumstances—their aché. Words, spoken or sung, carry aché, and thus the Lucumí language (derived from Yoruba) remains an important part of the religion. Similarly animal blood and certain key parts of sacrificed animals have aché to engage the orishas and the ancestors in human affairs. Santería conceives of the natural world and its aché through polarities: Heaven and earth, white and red, and male and female are just a few of the oppositions that organize the religion’s rituals.

RITUALS AND CEREMONIES
Santería’s followers mount complex ritual performances to interact with the orishas and other spirits. Through offerings of objects, foods, and animals, people “make ebó” to placate and petition the spirits. In divination they use traditional mechanisms (coconut pieces, cowrie shells, or palm nuts) to learn the disposition of the spirits and what sacrifices will create the appropriate balance between humans and the spirits. Most divination results in an odú, one of 256 possible divination signs thought to be spirits in their own right; odus contain proverbs, allegories, advice, and myths about the orishas, used to orient people to their circumstances. Specific songs, drum rhythms, and dance steps call the orishas to possess their followers, and the orishas use the human body to dance, sing, salute community members, and give advice. Through rituals and ceremonies, Santería initiates channel the aché of the orishas.

Through various initiations, people intensify their relationships with the orishas. The ceremonial receiving of consecrated necklaces (elekes) for the principal orishas creates a link between the individual spiritual head and those orishas; similarly it forges a bond between the individual and the initiators (godparents) and their ritual lineage. The warrior’s ceremony gives the new initiate sacred objects (fundamentos) through which to engage four important orishas who guide, protect, and invigorate the individual. The initiation of a new priest or priestess unites a large number of participants in a complex seven-day ceremony (kariocha) that begins a year-long process of transformation. These rituals forge intense, intimate connections between people and the orishas, and Santería often becomes an encompassing way of life.

Santería’s followers have often embraced other religious traditions and sources of divine power. Santería emerged in proximity to the Catholic Church, and the similar spiritual hierarchies made for easy comparisons: Orishas have long been compared with saints. While many scholars imagine Santería simply as a syncretism, a mixture between Yoruba religion and Catholicism, the religion focuses on worshipping the orishas and allows its followers to include or exclude links to Catholicism and other traditions, like the Afro-Cuban religions Palo Monte and Abakuá, which have their primary sources in other African cultures. People often extend the veneration of the ancestors to include spiritism (from France), and its rituals have evolved to include some specifically Cuban forms. Some people borrow ideas and symbols from Freemasonry and astrology.

CONTEMPORARY ISSUES
Cuban immigrants carried Santería beyond the island, and it now enjoys great popularity in the Caribbean, Mexico, Venezuela, Colombia, and the United States, while smaller active communities exist all over Canada and Europe. As in Cuba, the religion unites diverse people, transcending racial and economic differences. Discrimination against the religion has led to strong movements for legal recognition, and in 1993 the U.S.
Supreme Court recognized Santería as a religion and its followers’ right to sacrifice animals. Followers of the religion have begun exchanging ideas, images, and ritual practices with both Haitian Vodou and Brazilian Candomblé, each sharing strong historical ties to Yoruba religion. As Santería becomes a global religion spread by traveling elders, published texts, and the Internet, face-to-face relationships remain central to learning the worldview and rituals. Both the orishas and the odus provide flexible conceptual systems with which people can understand and respond to their diverse circumstances.

SARGENT, THOMAS 1943–

During the 1970s the pioneering work of the American economist Thomas Sargent focused on the implications of rational expectations for econometric research and policy-making. Expectations about the future are a key ingredient of economic decision making, and over the years economic theory has employed different models of expectations formation. The rational expectations hypothesis, initially formulated by John F. Muth Jr. in 1961, swept through macroeconomics during the 1970s. Robert Lucas Jr. and Thomas Sargent, in their 1972 and 1973 articles, led this revolution. The 1981 book by Lucas and Sargent reprints much of the key early literature, while a complete bibliography of Sargent’s works can be found in his 2005 interview with George W. Evans and Seppo Honkapohja.

Sargent exposed difficulties in standard procedures and showed how to formulate and conduct valid tests of central macroeconomic relationships under the rational expectations hypothesis. His contributions in this area include studies of the natural rate of unemployment, monetary neutrality of real interest rates, dynamic labor demand, hyperinflation, and tests for the neutrality of money in “classical” models. In the 1980s Sargent developed new econometric methods for estimating rational expectations models, which were presented in his 1980 and 1982 articles with Lars Hansen.

As put forward in articles with Neil Wallace in 1973 and 1975, Sargent also made several key contributions to theoretical macroeconomics, including the saddle-path stability characterization of the rational expectations equilibrium and the policy ineffectiveness proposition for monetary policy. His 1979 graduate textbook integrated these insights into an approach that viewed macroeconomic equilibrium as a dynamic, stochastic process. In later work Sargent continued to extend the rational expectations approach into new areas. Two prominent examples are his 1981 study, with Wallace, of the implications of the government budget constraint for inflation and his 1998 study, with Lars Ljungqvist, of the sources of the European unemployment problem.

Sargent’s contributions have not been confined to the development and application of the rational expectations paradigm. The standard formulation of rational expectations makes the strong assumption that economic agents have so much information that their forecast errors are just random noise. Sargent’s interest in the theoretical foundations of rationality led him in the 1980s to join a line of research called learning theory. In this approach, agents have an imperfect understanding of the economy and try to improve their knowledge over time. Albert Marcet and Sargent’s 1989 article showed, in a general setting, that econometric learning could converge to rational expectations equilibrium when certain conditions are satisfied. Sargent’s 1999 book called attention to the possibility of “escape routes,” that is, occasional large deviations from an equilibrium, and led to a surge of interest in persistent learning dynamics. The 1993 book by Sargent and 2001 book by George Evans and Seppo Honkapohja provide, respectively, an overview and a full treatise on learning and expectations formation in macroeconomics. Closely related to the research on learning are issues of robustness and model uncertainty, to which Sargent has
made key contributions, including his book with Hansen in 2003 and with Hansen and Thomas Tallarini in 1999.

In addition to the great intellectual depth and wide range of the contributions outlined above, Sargent has also done important research in economic history. Examples are his 1985 study on episodes of moderate and rapid inflations and his 2002 study, with François Velde, on monetary standards. Sargent discusses the different facets of his research in a 2005 interview with Evans and Honkapohja.

SARTRE, JEAN-PAUL
1905–1980

Jean-Paul Sartre was born in Paris on June 13, 1905, and died there on April 15, 1980. He studied philosophy at the École Normale Supérieure, achieving his doctorate in 1929, and then taught high school until the publication of his first novel, Nausea, in 1938. Sartre was a prisoner of war in World War II from 1940 to 1941, after which he founded a group of resistance intellectuals, socialisme et liberté, which he disbanded by the time of the 1943 publication of his most famous philosophical work, Being and Nothingness. Sartre became a celebrity at the end of the war, which enabled him to be a public intellectual on the world stage for a variety of causes that included fighting against anti-Semitism, supporting Third World liberation and workers’ struggles, protesting against the Vietnam War, and joining strikers in the student movement of the late 1960s. Some of Sartre’s causes, such as his support of the Algerian struggle for independence, led to assassination attempts on his life. Other causes, such as his support of communism without ever joining the Communist Party, led to attacks on him from extreme liberal and conservative critics. Sartre received many awards, two of which he refused—the French Legion of Honor in 1945 and the Nobel Prize in 1964. He was co-founder of the influential magazine Les temps modernes in 1945.

Although he wished to achieve greatness as a novelist and playwright, Sartre’s legacy is primarily as a philosopher, where he contributed to the study of freedom and the challenges it poses for understanding human existence. His writings from the 1930s until the late 1940s gave him a leading and permanent place in existentialism and phenomenology. Phenomenology is the study of things as understood as objects of consciousness. Sartre’s motto “Existence precedes essence,” argued for in Being and Nothingness, became a major theme of existential thought and a rallying cry against essentialism in the study of human beings. Human beings create themselves through living a biography, which is the only real self that will emerge at each person’s death. For a living human, choice is not only a constant possibility but is a precondition for itself. Even so-called choosing not to choose is a choice, and the act of choosing must in principle have preceded it. Sartre’s most famous play from this period, No Exit (1944), explored these themes in a situation, people encountering other people, with literally no material alternative to the “hell” of being forced together.

Many of Sartre’s writings in the late 1940s into the mid-1950s addressed existential themes in concrete situations. In Anti-Semite and Jew, he examined how the hating of Jews played a role in the construction of Jewish identity and the anti-Semite’s. This question of how humans create values that in turn create “us” was taken up in a unique genre (philosophical biography), in his demand for the writer to be politically “engaged,” and in his explorations of Marxism, reflected in works such as Baudelaire (1947), What Is Literature? (1947), and Critique of Dialectical Reason (1960). The Critique of Dialectical Reason explored the problem of agency in history and in developing existential Marxism, which is dialectical thought without determinism or the crushing of freedom.

Sartre, in effect, said good-bye to literature in The Words (1964), in which his hatred for his own class, the bourgeoisie (capitalist class), culminated in his rejection of literature as a bourgeois ideal in favor of devoting the rest of his life to political engagement. Although he continued to protest and sign declarations condemning human rights violations as long as his health permitted, this last period of Sartre’s life was marked by his conducting a sustained, multi-volume study of the life of the nineteenth century French novelist Gustave Flaubert, The Family Idiot (1971–1972), which he did not write for an audience but for himself. As with his works of philosophical biography, the role of bad faith in the formation of the self is illustrated in minute detail throughout. The text, like
SAT Test, the

many of Sartre’s projects, was not completed, which is appropriate for a philosopher whose life was a struggle against ever being pinned down and standing still.

SATIATION

The Oxford English Dictionary offers one definition of satiation to be the “point at which satisfaction of a need or familiarity with a stimulus reduces or ends an organism’s responsiveness or motivation” and thereby encompasses, in principle, the satiety of both needs and desires.

Neoclassical economics, however fuzzily its boundaries are conceived, sits ill at ease with the distinction between needs and desires. By conceiving of a generality in which the particularity of commodities is submerged in an abstract finite or infinite list, or simply postulated as a coordinate-free, infinite-dimensional space endowed with precisely specified mathematical structure, it obliterates the nineteenth-century distinction between use and exchange values. (The loci classici in the case of a finite list of commodities are Samuelson 1947; Debreu 1959; and McKenzie 2002. For an infinite-dimensional space of commodities, see the reference to Gérard Debreu’s 1952 paper on Valuation equilibrium and Pareto optimum in Debreu 1959 and relevant references in Khan 2008. The source for the use- and exchange-value is Marx 1967, who in turn takes it from chapter 4, book 1 of Smith 1776.) Once food, labor, money, and more popularly current reifications such as fidelity, trust, racial or ethnic characteristics, reputation, and the like are all seen under the same analytical rubric (in addition to Marx 1867, chap. 1, see Hill 1967 for the commodification of labor and Khan 1993 and 2002 for commodification more generally), “wants that spring from the stomach as opposed to those from fancy, appetites of the mind as opposed to hungers of the body” (Marx [1867] 1967, p. 43) are subjected to the same theoretical machinery and tamed by the same indiscriminate calculus, one blind to individual particularities of any commodity. It thus stands to reason that the subject sits ill at ease with the concept of satiation.

Thus perfect competition, as formalized in what is referred to as “general equilibrium theory,” the existence theorem, the two fundamental theorems of welfare economics, and through its adoption of the monotonicity assumption on preferences, the Debreu-Scarf theorem, all assume individual preferences to be non-satiated and the consumption set on which these preferences are defined to be unbounded from above (see Debreu 1959 and McKenzie 2002 for an explication of these results). To be sure, there is a literature in general equilibrium theory that addresses the assumption of satiation and thereby problems arising from compact consumption sets, but it surely constitutes a peripheral rather than a central stream (see McFadden 1969 and the literature that follows him in Winter 1969; Rader 1980; John and Ryder 1985; Weymark 1985; Mas-Colell 1992. I am supposing Debreu’s [1986] verbal proof of the first fundamental theorem to be also relevant here as well as the resurgence of the subject as exemplified in Martins-da-Rocha and Monteiro 2007 and their references.)

At the founding moment of the theory of optimal growth, Frank Ramsey did assume a “bliss point” (a point of satiation in the terms of this entry) for his representative agent (see Ramsey 1928 and its finite commodity generalization in Samuelson and Solow 1965). However,
by viewing this assumption as a response to an analytical difficulty rather than as a descriptive point of substance to be incorporated into the theory, subsequent work took two alternative routes. In a literature exemplified by Tjalling Charles Koopmans (1965), David Gale (1967), and William A. Brock (1970), the objective function was rendered well-defined by considering deviations from a golden-rule stock, a stock that ensures the highest constant sustainable rate of consumption and thereby ensuring the convergence of the relevant integral of the utility stream. Alternatively, as in Koopmans (1967) and Nancy L. Stokey and Robert E. Lucas Jr. (1989), the undiscounted framework is done away with altogether as something irrelevant to a regimen in which methodological individualism is rather aggressively prescribed to counter the possibility of any sort of governmental paternalism.

There is an irony in that Robinson Crusoe remains a hallowed figure for neoclassical economics even though his needs are limited (obviously so) and his desires have no ready outlet. (In addition to playing a role in Edgeworth 1881, Koopmans’s 1957 exposition of general equilibrium theory and the John von Neumann and Oskar Morgenstern 1953 criticism of this theory are based on Robinson Crusoe.) However, moving away from the creations of Daniel Defoe, Paul A. Samuelson, and Frank P. Ramsey, one ought perhaps not forget that the skeptical David Hume was crystal clear about the dampening effect of satiation on commerce and on the progress commerce could bring in its wake. In his influential essay “Of Refinements in the Arts,” he writes:

Riches are valuable at all times, and to all men; because they always purchase pleasures, such as men are accustomed to, and desire. In a nation where there is no demand for such superfluities, men sink into idleness, lose all enjoyment of life, and are useless to the public, which cannot maintain or support its fleets and armies, from the industry of such slothful members. Luxury, when excessive, is the source of many ills; but is in general preferable to sloth and idleness, which would commonly succeed in its place, and are more hurtful both to private persons and the public. (Hume [1742/1752] 1985, pp. 276, 272, 280)

The problem of scarcity of labor as a damper to the growth of colonial (plantation) economies brought about by satiation and self-sufficiency of native labor, and its possible cure in terms of a head tax levied in money, was well understood by colonial governments of all stripes in both the nineteenth and the twentieth centuries (see, for example, Mamdani 1976, chaps. 2 and 3), but even a half-adequate exploration of these theoretical and practical issues goes well beyond the ambit of this brief entry.

SATIRE

The word satire is often thought to be derived from the
Latin word satura, originally meaning the vessel used for
carrying harvest produce. It came to mean a mixture, and
then a mixed form of entertainment that people might
have at harvest time, consisting of songs, jokes, and other
kinds of humor. In its broadest sense, then, satire is a
mixed kind of humorous entertainment related to comedy
that focuses on people and their behavior.

In a more particular sense, satire is a literary form,
traced back to the Romans and in particular to the works of Juvenal (c. 50/60–127 CE) and Horace (65–8 BCE),
who both wrote about their own times, though in different
tones. Horace is characterized as more urbane and witty, Juvenal as more savage and critical. For these writ-
ers, a satire was a particular sort of poem with a strict form
and specific content. It was this definition that pervaded
English literature in the work of John Donne (1572–1631), John Dryden (1631–1700), Alexander Pope
(1688–1744), and Samuel Johnson (1709–1784) in the
seventeenth and eighteenth centuries.

From the Renaissance onward, the works of Horace and Juvenal, together with works by other great Greek and
Roman writers, including Homer (ninth to eighth century BCE), Virgil (70–19 BCE), and Ovid (43 BCE–
c. 17 CE), were the basis of an educated person's reading. The one hundred years from the Restoration in 1660 con-
stituted the great age of satire in English literature, known
as the Augustan Age, referring to the period in ancient
Rome when Augustus Caesar (63 BCE–14 CE) was the first
emperor. English writers produced their own translations
or versions of such classical works. For example, the
"Epistle to Arbuthnot" (1735) is Alexander Pope's pro-
logue to his own imitation of Horace's satires, and Dr.
Johnson based his London (1738) and The Vanity of
Human Wishes (1749) on Juvenal's Satires 3 and 10.

The eighteenth century, however, also saw the rise of
prose satire, especially in the works of Jonathan Swift
(1667–1745), whose Gulliver's Travels (1726) and A
Modest Proposal for Preventing the Children of Ireland from
Being a Burden to Their Parents or Country (1729) have
influenced most satirical writers since.

One significant reason for the pervasiveness and pop-
ularity of satire in England during the eighteenth century
may have been people's reactions to the disorder and divi-
sion that they experienced during the civil war of the
1640s. Satire became an effective method of drawing
attention to the ways in which human behavior falls short
of its ideal and of trying to correct that within an accepted
political and social framework. The job of the satirist,
therefore, became, as Jonathan Swift put it, "to cure the
vices of mankind." It is this moral purpose that underlies
great satirical achievements.

Along with this moral purpose, features that distin-
guish satire from other kinds of writing are its flexibility
of tone and its consistent use of wit and irony. The most
consistent target for satire in any period is hypocrisy, and
the predominant method is irony, where the reader always
has to be alert to the conflict between the literal and actual
meanings of what is being said. Hence, although the
golden age is perhaps the greatest age of satire in English
and although writing is the dominant form of satire, nev-
evertheless satire appears in many different periods and in
many different forms: writing, painting, and more
recently television and film.

It is often the case that effective satire can be
ephemeral. Particular examples of hypocrisy come and go
quickly, and so references can soon become dated as their
occasion slips from memory. Obvious examples may be
found in the contemporary television series *South Park* or *The Simpsons* or in political caricatures or cartoons.

There is also a sense in which satire is culture bound. Because it depends on wit and irony, it is neither accessible nor thriving in societies and groups where fundamentalism or literalism is the prevailing ethos. Throughout history there have been those who can only read literally and who have therefore missed the whole thrust of a satirical work. This was true of some readers of Swift’s *A Modest Proposal*, just as it has been true of some viewers of the satirical film *Borat: Cultural Learnings of America for Make Benefit Glorious Nation of Kazakhstan* (2006).

*Peter Buckroyd*

---

**SATISFACTION, RELATIONSHIP**

SEE Relationship Satisfaction.

---

**SATISFICING BEHAVIOR**

Herbert Simon coined the term *satisficing behavior* to describe human choice among alternative behaviors recognizing bounded rationality. The information-processing capacity of the human brain cannot examine all possible alternatives and their consequences for human satisfaction. Thus, Simon argued that satisficing was the dominant process, with maximizing playing a lesser role. Consumers, for example, might set an aspiration level and then begin to examine alternative purchases. When the aspiration level is reached, the person is satisfied, the search stops, and the purchase is made. Simon also applied his notion to games: “The players, instead of seeking for a ‘best’ move, need only to look for a ‘good’ move” (Simon 1955, p. 108). The aspiration level is conceived of as being learned in a series of choices. If the aspiration level is set too low, too many alternatives qualify, and perhaps the person is bored. If set too high, no alternatives may qualify, and the level is lowered. This makes preferences endogenous to ongoing experience and feedback rather than fixed as is often assumed in neoclassical economics. The new conception has not become standard among economists, but its use is growing.

Search among alternatives is necessarily selective and simplified by applying rules of thumb (heuristics) whether by a consumer or a business considering the mix of products to produce and methods of production. The interruption of routine is the occasion for examining behavior and goals. The learning involved in the examination of available means may cause goals (ends in view) to be modified. The problem agenda and problem representation are not given in advance but are worked out in the decision process affected by context and events affecting saliency of particular alternatives. This is consistent with a pragmatic view seeing means and ends as interdependent. “If there are goals, they do not so much guide the search as emerge from it” (Simon 1991, p. 367). Simon referred to this process as procedural rationality.

Humans are quite able to rationalize their current behavior. They can find a reason for what they are doing even if it was not in their consciousness before the behavior. The adjustment of aspiration level to the outcome of present behavior is both psychologically healthy and a possible source of disaster as habits can persist long after they are dysfunctional.

Some economists object to the concept of endogenous and evolving preferences because a moving target provides no deterministic standard for defining rationality. It is not easy to distinguish irrationality from learning. A business manager (or voter) may focus on one sub-problem rather than another over time. Saliency is affected by events, framing, context, and emotion. For example, environmental consciousness may result in management finding that former wastes can actually be recycled into profitable products. This would not happen if rationality were unbounded and all profitable alternatives were always being considered. Likewise, a consumer would not be influenced by product placement in the store or by advertising.

Consumers and producers do not have time to examine all possibilities. They collapse their experience into rules of thumb, and new observations cue behavior when the new data is put into a category to which a particular behavior is attached. The human brain can take in data and jump unconsciously to a conclusion and behavior. The fact that the reinforcement of behavior happens unconsciously does not mean that experience is irrelevant. The mind does not waste experience. The ability of the mind to fill in missing data is a strength and weakness. The brain takes in necessarily limited and uncertain data and fills in the rest by itself. This saves us from helpless indecision and at the same time exposes us to disaster when more observation would have led to a different behavior, perhaps affecting our very survival. In the face of very complex computational problems that challenge the capacity of the brain, this jumping to action may be better for profitability and survival than making a mistaken calculation. More data and more calculation are not necessarily better. When the payoff to one firm depends on the choices of other firms and the future is uncertain, the world may be much more predictable if most firms are
using the same rules of thumb than if all are calculating their best guesses.

Satisficing is consistent with many observed behaviors, such as simple markup pricing by business (requires less data than profit maximization), lexicographic preferences and choice (requires less data and calculation than utility maximization), and modular budgets. There is experimental evidence that many choices are intransitive. A modular budget allocating one's income initially to categories of expenditures produces what appears to an outsider as intransitive choices. Choices of goods then are made within these accounts without further reexamination of all feasible alternatives.

Consumers and businesses have multiple objectives, and making them commensurable would take considerable mental energy and calculation. The same could be said for attaching subjective probabilities to all outcomes. It is simpler to regard outcomes simply as likely or unlikely (outcomes the consumer or manager would be surprised by).

Bounded rationality implies decision costs. There are necessary tradeoffs between decision costs and better decisions. It is tempting then to suggest a calculated optimal search rule and conclusion of what is good enough. But such a rule has the same problem as that of the brain’s limitations.

Satisficing, which focuses attention on how managers and consumers actually make decisions, has implications for research. Scholars must get out of their armchairs to conduct field surveys; such research will always be incomplete and messy, but Simon argued that it would still be better than making assumptions. After surveying the literature, John Conlisk concludes in his 1996 article “Why Bounded Rationality?” that “psychology and economics provide wide-ranging evidence that bounded rationality is important” (p. 692). He argues that “models of bounded rationality adhere to a fundamental tenet of economics, respect for scarcity. Human cognition, as a scarce resource, should be treated as such” (p. 692). Satisficing is consistent with both observations. The point is not that optimization be wholly replaced with satisficing, but that human behavior will, as Conlisk notes, “vary by context, depending on such conditions as deliberation cost, complexity, incentives, experience, and market discipline” (p. 692).

SAVING RATE

The ability of a society to defer consumption from the present to the future provides resources for capital accumulation, which in turn creates a basis for increasing labor productivity and improving living standards. As such, positive national saving may beneficially contribute to a country’s economic development, although many other factors—such as the state of domestic demand and the effectiveness of financial intermediation—are also involved in influencing the extent to which this potential may be realized. (See the collection of papers in Setterfield 2002 on demand-led growth.)

The total saving undertaken by a country has three components:

<table>
<thead>
<tr>
<th>Components</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>a. Domestic private saving</strong></td>
<td>$Y - T - C$</td>
</tr>
<tr>
<td><strong>b. Public saving</strong></td>
<td>$T - G$</td>
</tr>
<tr>
<td><strong>c. International saving</strong></td>
<td>$X - M$</td>
</tr>
</tbody>
</table>

Income earned by households ($Y$), net of taxes they pay to the government ($T$), minus what they spend on goods and services ($C$) Any excess in the government’s tax revenues ($T$) over its expenditures ($G$) Any excess in the value of the country’s exports ($X$) over the value of its imports ($M$), which implies an accumulation of wealth abroad

Items (a) and (b) added together are known as “national saving.” To facilitate comparisons across countries and over time, saving levels are usually divided by disposable income (for domestic private saving) or national income (for public and national saving), to compute saving rates:

SEE ALSO Maximization; Minimization; Optimizing Behavior; Simon, Herbert A.

BIBLIOGRAPHY

A. Allan Schmid
Domestic private saving rate: \[\frac{(Y - T - C)}{(Y - T)} \times 100;\]

Public saving rate: \[\frac{(T - G)}{Y} \times 100;\]

National saving rate: \[\left\{\frac{(Y - T - C) + (T - G)}{Y}\right\} \times 100.\]

Changes in public saving can be expected to change private saving also because they affect expected after-tax income streams—the basis on which households make saving decisions. As a notable example, public pension programs such as U.S. Social Security generally reduce private saving, because people have less burden to accumulate their own savings to cover consumption in retirement. However, the extent to which private and public saving substitute for each other is open to debate. A contested conjecture is the idea of “Ricardian equivalence,” which holds that reductions in public saving are offset in full by increased private saving, because households will set aside resources to pay for the greater tax burden they know they will eventually face (Barro 1974). However, the empirical evidence on Ricardian equivalence is fairly mixed.

To see how a country’s saving relates to its investment, it is helpful to look at the following re-expression of the national-income accounting identity:

\[I = (Y - T - C) + (T - G) - (X - M)\]

This expression shows that funds for investment (I) can come from domestic private saving, public saving, and/or international dis-saving. The last term corresponds to the country’s trade balance. Because a country that has a trade deficit (X < M) must realize a capital inflow to cover it, the inflow supplements national saving as a source of finance for domestic investment. But if its exports exceed its imports, the surplus entails a capital outflow, reducing financing available for domestic investment in favor of wealth accumulation abroad. This “open-economy” aspect of the saving/investment link has been important for the United States in recent years: The level

of domestic investment has remained healthy despite low national saving due to the willingness of other countries to supply capital to the United States.

It is important to note that saving is a flow concept; that is, it measures the excess of income over spending in a given year, which adds to the country’s stock of wealth. Thus, a decline in household saving does not necessarily imply lower ability to finance consumption in the future—just a slower pace of accumulation of resources toward that end. A related implication is that household wealth can rise, even if saving falls, as long as asset prices are rising. This has probably contributed to the decline in household saving in advanced-industrial countries in recent years (figure 1): Because housing and stock markets have been strong, increases in asset prices have enabled households to scale their saving back while still accumulating wealth.

There are substantial, persistent differences across countries in their saving rates. As shown in figure 2, national saving rates in East Asia and the Pacific tend to be very high by international standards, ranging between 20 and 30 percent in the past twenty-five years. In contrast, saving rates in high-income countries of the Organization for Economic Cooperation and Development (OECD) have drifted down from about 10 percent in 1980 to 5 to 7 percent in the mid-2000s. In Latin America and the Caribbean, saving rates tend to track those of the high-income OECD countries, whereas in South Asia they are higher (10–15%). In sub-Saharan Africa and especially the Middle East and North Africa, national saving rates fluctuate appreciably from year to year, in good part because fluctuating prices of commodity exports impart volatility to public saving.
While the causes of these cross-country differences are not well-understood, several factors are probably involved. First, the “life-cycle” theory of saving (Ando and Modigliani 1957) suggests an important role of demographic variables. The basic proposition of the life-cycle view is that people borrow against future income when young, save in their high-earning middle-age years, and spend down their assets in retirement. Thus, for example, population aging in the advanced-industrial countries might be expected to drive down private saving rates (OECD 1998). Second, periods of rapid economic growth tend to be strongly associated with increased saving, perhaps because consumption takes a while to catch up to permanently higher incomes (Carroll and Weil 1994). Third, the introduction of government social-insurance programs (e.g., unemployment, welfare, disability) alleviates people’s need to “save for a rainy day,” which may edge national saving down. Fourth, the development of credit markets also reduces precautionary motives to save, as borrowing can be used instead of dissaving to cover consumption needs (Japelli and Pagano 1989). Finally, there are also differences across cultures in the priority placed on saving for the future versus living for today, although it is difficult to disentangle effects of culture on saving from those of other variables.

A growing body of research examines how saving rates vary with household characteristics, using survey data (see Browning and Lusardi 1996 for a valuable review). Many studies find that saving tends to be higher among middle-aged households, ceteris paribus, consistent with the life-cycle view. Yet there are also lots of findings that are hard to reconcile with life-cycle theory—for example, that good-sized fractions of households hardly save at all, that older households tend to dissave “too slowly” relative to their life expectancies, and that very rich households save entirely too much for life-cycle motives to be the whole story. Thus, researchers have explored numerous extensions to the life-cycle model to see whether its fit to the data can be improved. These extensions include the possibility that liquidity constraints or asset-limits for social-insurance programs explain low saving among low-income households (Zeldes 1989; Hubbard, Skinner and Zeldes 1995); that uncertainty about time of death and/or bequest motives lie behind slow dissaving in old age (Davies 1981; Abel 1985); and that the very wealthy accumulate wealth for wealth’s sake, rather than for the future consumption it assures (Carroll 2000). Nonetheless, given uncertainties about whether intertemporal optimization is a good description of consumption and saving behavior, economic research is also branching out to explore “behavioral” views of household saving, in which households use heuristics to make informationally complex decisions and/or struggle with problems of self-control, in which they know they should be saving for the future but are unable to start doing so today (Shefrin and Thaler 1988 and Laibson 1997). Behavioral approaches may be especially valuable for investigating whether households save adequately for retirement (Aaron 1999)—which in turn is important for evaluating proposals to shift responsibility for retirement saving back to the private domain.

Say, Jean-Baptiste

Martha A. Starr

SAY, JEAN-BAPTISTE

SEE Say’s Law.

SAY’S LAW

The French economist Jean-Baptiste Say, in his A Treatise on Political Economy (1803), developed a theory of market activity that sited the source of the demand for products not on the quantity of money possessed by individuals but rather on the value of the quantity of products that those individuals supplied. People receive money for producing goods with the purpose of immediately purchasing goods of an equivalent value: “A product is no sooner created, than it, from that instant, affords a market for other products to the full extent of its own value” (Say 1971, p. 134). Money itself has no bearing on the relationship between the production of goods and the quantity of goods that they could fetch. It was in this sense that one might infer from Say’s analysis that “supply creates its own demand.” Changes in production by one individual thereby affect production in many markets: “The success of one branch of commerce supplies more ample means of purchase, and consequently opens a market for the products of all the other branches; on the other hand, the stagnation of one channel of manufacture, or of commerce, is felt in all the rest” (Say 1971, p. 137).

SAY’S ECONOMICS

Say’s views on public policies emanated directly from his understanding of the mechanism by which an economy thrived and grew. The state should not put into effect any policy that would prevent producers from keeping their profits or for income to be diverted to unproductive consumption rather than savings. Anything that promoted the ability to produce more implied the enhanced ability of everyone else to produce and consume more goods.

The broader definition of Say’s Law as it is customarily accepted relates to the idea that a general glut in commodities for the economy as a whole is impossible. Say, however, at least in the Treatise, never imagined the possibility of there being a general glut of all commodities, except as an aside (Baumol 1977, p. 156; Kates 1998, p. 24). He did recognize, though, that in real time one’s ability to make a purchase was not automatically equal to what he had intended when measured by the value of the product at the time of production. Gluts in “superabundant commodities,” as Say called them, might occur if “it has been produced in excess abundance, or because the production of other commodities has fallen short” (1971, p. 135). Neither of these causes could be attributed to anything economy-wide. Rather, gluts in any one commodity, even the superabundant kind, occurred, at the end of the day, not because of a dearth of money but because of a dearth of supply.

It was left to James Mill (1808) and Robert Torrens (1821) to elaborate on Say’s framework, allowing them to conclude that a general glut in the economy as a whole was a logical impossibility. Mill in turn influenced Say’s understanding of this issue, which he laid out in later editions of his Treatise (see also Say 1967 [1821]). Torrens’s explanation was more consistent with Say’s perspective in that an economy-wide downturn could be explained by “miscalculations” and particular gluts in the market (Kates 1998, p. 36).

What emerged from these elaborations of Say’s original analysis was a generally held conceptualization that one could think about a price system that regulated the flow of resources and goods supplied within a theory of markets. Moreover this price system was understood to be independent from the identification of the absolute nature of those prices, which were determined solely by the stock of money at any moment of time—the so-called classical dichotomy.

KEYNES’S ECONOMICS

In 1936 John Maynard Keynes, in his The General Theory of Employment, Interest, and Money, criticized this tradition of economic theory and policy that began with the writings of Say, what he referred to as “classical economics.” The intention of Say and others to show that output (and employment) in the economy emanated from activity at the level of the individual firm suffered from a logical flaw, in Keynes’s opinion, because the specification of the functional relationships at the level of the individual could be posited only if it was assumed that output as a whole was given and unchanging. Thus the method of describing an economy in terms of the behavior of individual supply had no theoretical validity except when output as a whole was fixed at the point where all resources were employed. Classical economics could explain relative movements in output and employment, but they had no method for considering changes in the level of output and employment as a whole. This conclusion followed from the view held by Say and his followers that no one would hold money as a store of value; money therefore had no essential properties in and of itself. Keynes therefore
wished to consider, instead, a monetary economy “in which changing views about the future are capable of influencing the quantity of employment and not merely its direction” (1971, p. xxii).

From that criticism of what he considered to be an illogical theoretical system, Keynes sought to develop an alternative framework of analysis with his theory of effective demand. Here, he believed, one could think logically about the relationship between activity at the level of each individual or firm and industry as a whole (his alternative dichotomy) but without the necessary presumption that output was given at full employment. Keynes’s reframing specified those relationships in a form such that each realm (the individual firm or industry and industry as a whole) existed in the context of the other. Either could remain stable or fluctuate without any stipulation that whatever was produced in the economy had to use all of the resources that were available. Keynes therefore felt that he had formulated a general theory of employment and output that was not predicated on a price system within a theory of markets in the tradition of Say, independent of the determination of absolute prices in general. Instead, he set the goal of bringing questions of money and prices back into the theory of employment and output as a whole.

This Keynesian revolution, which was intended to overturn the economic theory and policy built on Say’s Law, never happened, at least according to one of Keynes’s closest students and colleagues, Joan Robinson. Keynes’s alternative vision of a monetary theory of production, as well as his mode of reasoning upon which that vision was built, was never embraced by the discipline. Economic theory and policy in the early twenty-first century therefore remained entrenched firmly in the dichotomous framework by which resource allocation is determined in a system of relative prices emanating from the rational behavior of individuals, while absolute prices are determined by the quantity of money.

Modern theoretical debate has been reduced to analyzing the speeds at which prices and quantities adjust. New classical economists, on the one hand, assume that prices adjust instantaneously, meaning that questions of quantity adjustments are never at issue—the classical dichotomy is therefore in place at all times, leading to a clear and limited set of policy prescriptions that eschew any form of discretionary public intervention. The only tool of macroeconomics is the control of inflation through the proper control of the money stock. New Keynesian economists, on the other hand, admit that markets may fail to resolve themselves in the short period, which could lead to greater movements in output than in prices. It should be emphasized that questions of employment and output by new Keynesians are still conceptualized and therefore framed as a mere generalization of individual market activity, the approach Keynes found to be illogical. In these intervals the classical dichotomy might very well be violated, perhaps necessitating policy intervention beyond just monetary policy. But even for most new Keynesian economists, it is just a matter of time before markets make their necessary adjustments, reestablishing the separation of real and monetary sectors.

Both schools of thought do recognize that institutional barriers to full resolution persist even over the longer period. This recognition has led them to construct theoretical edifices such as the “natural rate of unemployment” and the non-accelerating inflation rate of unemployment, allowing them to fit reality back into their theoretical vision. Once resolved, there has emerged a confluence of views on long-term public policies for both new classical and new Keynesian economists limited to the control of inflation by the monetary authorities and the shedding of external barriers to the free market mechanism, allowing it to resolve itself fully.

One should not be surprised that policy to promote real economic growth has led to legislation that intends to break down all barriers that might have prevented those who prospered (who made profits either by productive activity or in the form of dividends from equity holding) from keeping the greatest portion of those profits. For they who are the most successful in the market can be expected to increase supply by the greatest amount, opening a market for the products of all the other branches” (Say 1971, p. 137). These supply-side policies have been disavowed by some new Keynesian economists, although the motivation for their objections has come from political rather than economic foundations. The vision of economics and economic policy has progressed little indeed since Say’s Treatise, when he suggested that policies should not exist that take away profits from producers unnecessarily and that savings (immediately translating into investment because people do not want to hold onto their money/profits longer than they must) should be encouraged over unproductive consumption.

Roy J. Rotheim

SCALES

In the social sciences, it is often important to measure attributes of individuals that are not readily observable, such as beliefs, attitudes, emotional experiences, and personality traits. Because such attributes are not readily observable, social scientists rely on scales that allow individuals to report the extent to which they possess or experience them.

SCALES OF MEASUREMENT

A scale provides both qualitative information and quantitative information about an attribute. The most basic type of scale has an individual simply indicate whether he or she possesses a certain attribute. This type of scale provides only a qualitative indication of the presence or absence of the attribute and is considered to have a nominal scale of measurement. A second type of scale has the individual indicate the presence or absence of the attribute in question and the quantitative amount of the attribute he or she possesses. For example, a scale of this sort could ask individuals to indicate how much they like ice cream by selecting a number from one to three, where one represents not at all, two represents moderately, and three represents extremely. This type of a scale has an ordinal scale of measurement, which provides a rank-order quantitative value of the degree to which the attribute is present. Note that even if these values are related to one another in a rank ordering, the psychological distance between neighboring values may not be equivalent (e.g., in the example above, the psychological difference between not at all and moderately may not be the same as the psychological difference between moderately and extremely). When a scale provides rank-order values of an attribute and equal psychological distances between neighboring values, the scale has an interval scale of measurement. Finally if a scale has equal psychological distances between neighboring values and a value that reflects the complete absence of the attribute in question, then the scale has a ratio scale of measurement. Most scales used by social scientists are nominal or ordinal in nature because it is very difficult to objectively determine if the psychological distance between neighboring scale values is truly equivalent.

TYPES OF SIMPLE SCALES

Two general types of non-nominal scales are used in the social sciences. The first type is the Likert scale, which consists of labeled discrete values located between two labeled endpoint values. The ice cream scale described above is an example of a Likert scale. The second type is the visual analog scale, which consists of either discrete unlabeled values or a continuous unlabeled line between labeled endpoints. Likert scales are ordinal and provide only a limited number of values from which to choose, but they yield information about the qualitative degree to which an individual possesses the attribute in question. In contrast, continuous visual analog scales provide a large number of potential values from which to choose, but they yield little information about the qualitative degree to which an individual possesses the attribute in question. Some believe that visual analog scales have an interval scale of measurement, whereas others argue that they possess only an ordinal scale of measurement.

COMBINING SCALES INTO INVENTORIES

Ratings on individual scales are often combined to form an inventory. Inventories are essential when assessing complex attributes. Creating an inventory ensures that an attribute is measured in its entirety, which may be difficult to accomplish with a single scale. In an inventory, individuals respond to a number of statements using the same scale of measurement. For example, an anger inventory may be created by asking respondents to rate how angry, irritated, and mad they feel, each on a discrete visual analog scale. Each statement in the inventory must refer to a single object in order to minimize confusion. It is also useful to include statements that require responses that are the opposite of other statements in the inventory (e.g., How much do you like ice cream? vs. How much do you hate ice cream?) in order to reduce the likelihood that individuals are reporting responses without paying close attention to the scale items.
RELIABILITY AND VALIDITY

A scale or inventory must be both reliable and valid. Reliability is the extent to which an individual makes similar ratings across time using the same scale or, in the case of an inventory, the similarity of an individual’s responses to related items within the inventory. Assuming that a scale or inventory is reliable, it must also have high construct validity. Construct validity is the extent to which the scale or inventory accurately measures the attribute in question. High construct validity can be demonstrated in a number of ways. First, one can establish convergent validity by showing that responses on the scale or inventory are positively associated with patterns of behavior or responses on another scale or inventory believed to measure the attribute or a similar attribute. Second, one can establish discriminant validity by showing that responses on the scale or inventory are not positively associated with patterns of behavior or responses on another scale or inventory believed to reflect an unrelated attribute.

SCARCITY

The term scarcity implies a lack of a given thing, of it not being plentiful or easy to find. It is a term that does not impress one as having anything to do with science. For economics, however, scarcity is the starting point, a state of affairs that gives rise to a series of deductions that build the whole formal structure of economic science.

In the somewhat technical jargon of economics, scarcity represents a situation in which the existing means (resources, goods, etc.) are not sufficient for the achievement of all existing ends (goals, wishes, desires, etc.). Under such circumstances, it is indispensable to make decisions about which ends one will strive to achieve and which ones will be left unattended to. All such decisions imply the existence of some benefits (or utility), associated with the achievement of certain ends, and of some costs, corresponding to the benefits associated with the achievement of ends that were forgone. It is in terms of benefits and costs that economists conceive of every decision, and it is through benefits and costs that changes in external conditions have an impact on human behavior.

It is easy to see that in a world where everything was abundant—where scarcity would not apply—all the above categories would be meaningless and economics would not exist. However, scarcity does exist, and it is not a mere empirical coincidence. It is a condition of life as human beings perceive it, and as such it cannot be undone. One can certainly imagine having many times more resources at one’s disposal and having more of every good than could possibly be enjoyed (although humans are very far from experiencing this scenario). And yet this would not free one from having to make any decision whatsoever: One would still be forced to choose between different ways of enjoying all those superabundant supplies of goods, for human beings cannot engage in mutually exclusive activities. Thus, due to the inescapable scarcity of time, it is not possible to conceive of a world in which scarcity would not be known. This is why most scholars (or economists, at any rate) consider scarcity to be a universal and necessary human condition.

The presence of the scarcity problem people face, and in particular the need for trade-offs in dealing with scarcity, is reflected in popular common-sense adages such as “there ain’t no such thing as a free lunch” (coined by Robert A. Heinlein in The Moon Is a Harsh Mistress [1966] and popularized in economics by Milton Friedman). In economic science, it is typically illustrated by the “production possibility frontier,” a two-dimensional graph showing maximum amounts of two goods (e.g., “guns and butter”) that can be produced with given resources. The frontier, which graphically represents the finiteness of options, also illustrates the concept of cost, for it shows that as long as all resources are being used, the output of one good can be increased only at the expense of a lower output of the other good.

While scarcity may be considered an omnipresent condition of human life, it is possible to view human behavior as a struggle to reduce its acuteness. The extent to which people are successful at narrowing the gap between means and ends can, in turn, be seen as a subjective degree of wealth as perceived by the person in question.

In economics, this process of reducing the problem of scarcity can also be shown with the help of the production possibility frontier. A more efficient use of resources allows for greater production of both goods, which in turn allows for more ends to be achieved and (with given wants) gives rise to a feeling of being wealthier than...
before. This more efficient use of resources, graphically pictured as an outward shift of the frontier, is usually attributed to three different sources of improvement: (1) improvement in human capital, (2) accumulation in physical capital, and (3) human cooperation (a division of labor and exchange).

The omnipresence of scarcity and its central position in orthodox economics has been challenged both from within economics and from without it. The attack from within has come from progressively minded economists. Believers in the enormous capacities of technological progress and the human mind have claimed there is a possibility of doing away with scarcity at some point in the future by devising ever more efficient ways of using resources, and thus making goods so plentiful as to accommodate all practical needs.

While this theory is usually propounded by some lesser lights among economists, there have been notable exceptions. John Maynard Keynes, for example, insisted that scarcity is kept unnecessarily high by an artificially high interest rate. In a similar vein, John Kenneth Galbraith, not incidentally an admirer of Keynes and a well-known economist as well, undermined the importance of scarcity with his concept of the “affluent society.” Our society is supposed to have reached a sufficient degree of affluence to enable it to provide all the genuine needs people may have. The remaining feelings of scarcity are a product of artificial wants, as Galbraith would have it, created by advertising. None of these authors, however, have attacked scarcity directly, nor have they claimed that scarcity would cease to exist altogether. Instead, they have alluded to its man-made, and thus unnecessary, nature, and to a possibility of its substantial elimination through proper government policy.

From outside of economics, the assault on scarcity has come from anthropologists such as Marshall Sahlins. Their point is that a large degree of affluence did exist before the advent of civilization, among the Paleolithic hunter-gatherers. They show that, contrary to conventional wisdom, such societies did not struggle, but rather enjoyed a life of relative plenty, with more leisure time and (some claim) greater happiness than an average modern person would have today. All this, of course, is due to their having had drastically more modest needs.

While these ideas, just like those of Galbraith, can be justly considered as criticism of the modern consumer civilization, they do not show the logical possibility of a world without scarcity. Even the most austere monks living on water would surely have to make some decisions, if only what to meditate about. Thus, these criticisms may well play down the necessity of the scarcity in human affairs (i.e., its severity and centrality in the human mind), but they will hardly cause the orthodox economics to crumble under its weight.

**SCARR, SANDRA WOOD 1936–**

Sandra Wood Scarr’s career as a psychological scientist spanned more than four decades. During that time, she engaged in scholarly pursuits dedicated to examining genetic influences on development and the importance of quality child care.

Scarr was born in 1936. She received her PhD from Harvard University in 1965 with a dissertation that examined genetic contributions to personality development in identical and fraternal female twins. Scarr’s findings, that sociability and activity level were genetically linked, challenged the mainstream belief at the time that environmental influences predominantly affected development. Following graduate school, Scarr held academic positions at the University of Maryland (1965), the University of Pennsylvania (1966–1971), the University of Minnesota (1972–1975), Yale University (1977–1983), and the University of Virginia (1983–1995). She retired in 1995.

While at the University of Pennsylvania, Scarr examined the genetic and environmental predictors of identical and fraternal twins’ intellectual development. Although genetic influence accounted for variations in intellectual development overall, environmental influences were more pronounced for black children than white children. Scarr attributed these differences to disparities in the relative opportunities afforded to the white versus the black children.
While at the Institute of Child Development at the University of Minnesota, Scarr initiated the Minnesota Adoption Projects with the psychologist Richard A. Weinberg. One of their most controversial and misinterpreted collaborative studies was the Minnesota Transracial Adoption Project, which examined the IQ of 101 black children adopted into white families. Their findings revealed that rearing environments do affect children's performance on intelligence tests; specifically, IQ scores of the black children reared in white families relative to those reared in black families were significantly higher. Longitudinal examinations of these same children suggested that the effects of rearing environments are strongest in early childhood and dramatically decrease in adolescence. Although alternative explanations for the decrease in IQ scores may be attributable to environmental factors, such as conflicts surrounding dating and social identity during adolescence or the conflicts that might arise for nonwhite children living in a white environment with their white parents, the reduction of environmental influences in adolescence is well supported in the behavioral genetics literature. Scarr’s book *Race, Social Class, and Individual Differences in I.Q.* was published in 1981.

Scarr extended her work on gene-environment interactions through a series of theoretical and empirical papers. She and her colleagues proposed that the environments actively selected by individuals affect the genetic expression of characteristics such as personality. Further individuals’ characteristics evoke particular reactions from others in one’s environment. Thus the expression of a person’s genes has not only passive and active effects but also evocative effects.

Another branch of Scarr’s research program was geared toward improving the quality of child care environments. Scarr’s research with Margaret Williams, which demonstrated that stimulation practices (e.g., music exposure and rocking) had beneficial effects on premature infants’ subsequent growth and development, revolutionized the standards of neonatal care practices in hospital settings.

In 1984 Scarr published *Mother Care/Other Care*, for which she received the American Psychological Association’s (APA) National Book Award in 1985. In this book Scarr identified deciding factors that influenced mothers’ reasons for entering the workforce as opposed to remaining at home. She also challenged the belief that maternal employment had negative effects on young children’s development and maintained that children can be well cared for by someone other than their parents. Her work also addressed the benefits of high-quality child care, particularly the importance of low child to caregiver ratios and stimulating day care environments.

In 1990 Scarr began serving on the board of directors of KinderCare Learning Centers, where she eventually served as chief executive officer from 1995 to 1997. Scarr moved to Hawaii after an investment firm purchased KinderCare.

Throughout her career, Scarr earned numerous awards and honors for her contributions to the science of psychology. In 1988 she received the first APA Award for the Distinguished Contribution to Research in Public Policy, and in 1989 she was elected to the American Academy of Arts and Sciences. Scarr’s professional service included serving as the associate editor of *American Psychologist*, as editor of *Developmental Psychology*, and as cofounding editor of *Current Directions in Psychological Science*. Scarr also held several key leadership positions, including serving on the APA’s board of directors, as president of the Society for Research in Child Development, and as president of the American Psychological Society.

Ultimately, although controversial, Scarr’s contributions to the study of gene-environment interactions and the importance of quality child care defined and paved the intellectual path for contemporary and future generations of psychological scientists.

**SCHACHTER, STANLEY**

1922–1997

Stanley Schachter was trained as a social psychologist at Yale University, Massachusetts Institute of Technology, and the University of Michigan, where he received his...
Schachter went on to study cigarette smoking, where he eventually adopted a radically “internal” perspective, arguing that psychological factors affect smoking only insofar as they affect urinary pH, which in turn influences nicotine reuptake into the bloodstream. He also studied the psychology of money and verbal dysfluencies before retiring in 1992. His legacy is his blend of creativity and the dogged pursuit of data to support his intuitions, which pleased him most when they challenged conventional wisdom.

SCHATTSCHEIDER, E. E.
1892–1971

Elmer Eric Schattschneider received his PhD from Columbia University in 1935. For the remainder of his academic career he taught primarily at Wesleyan University in Middletown, Connecticut, where he was John E. Andrus Professor of Government. He was president of the American Political Science Association from 1956 to 1957. He is best known for his work on political parties, which he used as a prism through which he built a powerful and, despite numerous criticisms, enduring argument on the nature of modern democracy.

Schattschneider first presented his argument regarding parties in Party Government (1942). It is probably the...
most often cited, the most controversial, and the single most influential work on American political parties penned to date. His thesis was that modern democracy is unthinkable except in terms of political parties because they are the umbilical cord that links citizens to their government. If that cord is cut, he thought, both government and citizens would shrivel and die as components of a democratic polity. The weakness of the founding arguments, in The Federalist for example, is that the founders' conception of government was not only undemocratic but, because it was essentially nonpartisan, was also built on unrealistic assumptions about democracy. American government became progressively democratic as parties developed. Schattschneider became the best-known advocate for the "responsible party" school in American government, the idea that parties should formulate policy proposals and present them to the voters, thus making elections occasions for major policy decisions. The measure of democracy would largely consist of the ability of parties to translate these policy choices made by the electorate into policy government. The cycle of democracy was one of responsible parties, electoral choice between parties, and party organization of government after the election. Schattschneider further refined and developed his party arguments when he was elected to chair the American Political Science Association Committee on Political Parties. The committee report, Toward a More Responsible "Two Party" System, was published in 1950.

The argument for responsible parties was challenged on several grounds. First, responsible parties would necessarily require that ideology, liberal or conservative, would be the organizing principle of policy proposals rather than the more pragmatic consideration of simply winning elections. Responsible parties would intensify political conflict over competing policies. Consensus political scientists argued that the natural tendency of political parties in a winner-take-all system would be toward the center of political gravity because voters would be distributed with varying intensity along a continuum that ranged from liberal to conservative and not merely cluster at the extremes. Second, Schattschneider was challenged on the very purpose of parties in the first place. Do parties exist merely to promote policy government, or do they also serve as intermediary institutions between citizens and their government that should moderate conflict rather than exacerbate it? American political parties, it was pointed out, developed after the ratification of the Constitution and did not so much create a democratic government as they helped provide a means whereby citizens could find a measure of civic peace within a framework that was largely popular from the outset. The founders evidently thought democracy could be conceived of outside the framework of parties.

A measure of Schattschneider’s influence is in the literature of political parties since his most important work. It is almost impossible to discuss American political parties in terms of their purpose and role in a democratic system without reference to his arguments. The resulting quarrels over the nature of parties led Schattschneider to publish The Semisovereign People: A Realist’s View of Democracy in America (1960). It is a deceptively short book—an essay really—that tries to get at, as he puts it, “what makes things happen” in American government (Schattschneider 1960, p.v.). This is his most philosophical work. His conclusion was that “the role of the people in the political system is determined largely by the conflict system, for it is conflict that involves people in politics and the nature of conflict determines the nature of public involvement” (Schattschneider 1960, p. 126). The people, he thought, are powerless unless the system is competitive, and parties are the institutional agents of that competition. The Semisovereign People is a fitting epitaph for the work of one of the most influential scholars in American political science.

Schattschneider was right to see parties as the engine of policy changes and innovation. He was also right to see in the development of modern party government a significant departure from the founders’ conception of popular government. The extent to which parties are or should be responsible in the sense he advocated is a more debatable proposition.

SCHEMAS

A schema is a knowledge structure containing the generic representation of a concept. For example, a schema for chairs includes a flat platform to sit upon, four legs, and a back. While not all chairs fit this description, schemas can be modified to include other versions of the concept (e.g., a three-legged stool or a chair with no legs). Schemas can be held about any concept, are often arranged hierarchically, and affect perception, cognition, and memory.

The concept of a schema can be traced to Immanuel Kant (1724–1804), who in 1781 discussed the concept in Critique of Pure Reason. More recently, Frederick Bartlett, in 1932, had participants read foreign folktales and later asked them to recall the details. When reading a Native American folktale, non–Native American participants often changed “canoe” to “boat,” left out prominent themes, and made the story more European. Bartlett suggested that memory was not fixed, but changed as people actively reconstructed episodes to fit their preexisting schemas.

Jean Piaget used schemas to explain how children acquire new skills and learn to interact with the world. After being scared by a large, aggressive dog, a child may develop the schema that four-legged creatures are dangerous. When confronted by similar dogs, the child may react with fear. Piaget referred to the application of an existing schema to a different stimulus as “assimilation.” However, when exposed to a small, well-behaved dog, the child might react positively. Piaget referred to the modification of an existing schema (or the creation of an entirely new schema) to fit a new stimulus as “accommodation.” Piaget suggested that assimilation and accommodation are the bases of adaptation (i.e., learning) and define the stages of cognitive development.

There are many different kinds of schemas (what follows is by no means an exhaustive list): role schemas (e.g., the role of a student vs. that of a teacher), event schemas (e.g., what happens at a cocktail party vs. a football game), self schemas (i.e., what we think of ourselves either globally or in specific domains), relationship schemas (e.g., the relationship with one’s mother vs. one’s best friend), trait schemas (e.g., what shy people are like vs. outgoing people), procedural schemas (e.g., how to make coffee vs. how to put gas in a car), stereotypes (i.e., schemas concerning members of social groups; e.g., the cognitive ability of the young vs. the elderly), and scripts (i.e., how to act in certain situations; e.g., ordering food at a fast food restaurant vs. a fine dining establishment).

Schemata are thought to be functional. They help to organize and understand the world and to fill in informational gaps. They also reduce ambiguity and serve as memory guides, directing our attention to relevant aspects in the environment. However, the overuse of schemas can result in stereotypes. For example, a 2001 study by Brian K. Payne found that when participants were shown a picture of a person’s face followed by a picture of either a tool or a gun, the race of the face influenced whether people misidentified pictures of tools as weapons. Even though participants were told to ignore the first picture showing a person, they were more likely to report tools as weapons when the pictures were paired with black faces. This tendency for previously viewed stimuli to activate schemas and influence perceptions—even in very different situations—is known as priming.

SCHIZOPHRENIA

Approximately one percent of the population suffers from schizophrenia, a severe and persistent mental disorder that is characterized by a wide range of cognitive, social, behavioral, and emotional symptoms and that has been identified by the World Health Organization as one of the ten most debilitating diseases. As specified in the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV-TR) (APA 2000), positive symptoms of schizophrenia include hallucinations, delusions, disorganized speech, and grossly disorganized or catatonic behavior. Negative symptoms include affective flattening (a lack of emotional response), alogia (poverty of speech), and avolition (an absence of motivation). In addition, impairment is present in one or more major areas of functioning, such as work, interpersonal relations, or self-care. Subtypes of schizophrenia...
The vulnerability-stress model offers a useful way of integrating current thinking about schizophrenia. The model assumes that schizophrenia involves a biogenetic vulnerability or predisposition to develop the disorder. A range of biological and psychosocial factors can interact with this vulnerability to affect the manifestation and course of the illness. Certain risk factors, such as substance abuse, are associated with symptom exacerbation and an increased likelihood of relapse. Protective factors, such as social support and coping strategies, can ameliorate the symptoms of the disorder and make relapse less likely.

Both diagnostic and functional assessment are important in designing individualized treatment and rehabilitation plans. The use of standardized instruments, such as the Structured Clinical Interview for DSM-IV-TR (SCID), can increase the likelihood of an accurate diagnosis. Functional assessment focuses on potential deficits in skills and resources that can result in impairment in the ability to function at home, work, and school.

Effective and efficacious psychopharmacological and psychosocial treatments have become available during the past three decades. Since the late 1970s there has been an increasing development of new antipsychotic medications. Evidence-based psychosocial interventions have replaced older psychodynamic approaches and accelerated community reintegration of patients who were formerly institutionalized. The benefits of antipsychotic medications include decreased symptoms, reduced risk of relapse, and increased response to psychosocial interventions. Generally combined with medications, psychosocial interventions have demonstrated benefits in the areas of relapse and rehospitalization, housing stability, competitive employment, social functioning, psychotic symptoms, and substance use disorders (Mueser et al. 2003).

Evidence-based psychosocial interventions include assertive community treatment (ACT), family psychoeducation, supported employment, training in illness-management and recovery skills, and integrated dual disorders treatment. The ACT model was developed to meet the needs of individuals with a history of high service utilization or severe functional impairment. Services are provided on a twenty-four-hour basis in natural living environments by multidisciplinary treatment and rehabilitation teams. Family psychoeducation generally includes services both for people with schizophrenia and for their family members. Components include education about mental illness and its management, skills training, and social support. Supported employment services include rapid job search rather than extensive prevocational assessment; competitive wages for jobs in integrated settings; ongoing support once a job has been obtained; and combined vocational and mental health services. Interventions that target illness management and recovery are designed to help people with schizophrenia acquire the information and skills needed to collaborate in their treatment, to minimize the effects of the disorder on their lives, and to be able to pursue personally meaningful goals. Integrated dual disorders treatment focuses on substance use disorder, which is the most common and clinically significant comorbidity associated with schizophrenia. Integrated mental health and substance abuse programs provide simultaneous treatment of both disorders in a single setting. Social and cultural variables are relevant to the etiology, epidemiology, phenomenology, course, and prognosis of schizophrenia.

Because schizophrenia seemed more prevalent in lower socioeconomic groups, earlier sociologists postulated social stress as a casual factor; others attributed clustering in poor areas to downward social drift. Although psychogenic or sociogenic theories have largely been nullified by biogenetic findings, other correlates of the social environment have apparent etiological significance. For example, maternal exposure to wartime famine or the type A influenza virus during fetal development predicts significantly higher risk for later development of schizophrenia.

World Health Organization studies have consistently shown that despite standardized diagnostic criteria, the prognosis for schizophrenia is significantly better in developing countries than in the industrialized West. Some analysts attribute this to the presence of less virulent variants of the syndrome. Others point to cultural variables that mitigate the impact of schizophrenia in traditional societies, including magical causal theories that view mental disorders as temporary. In developed countries, in contrast, the person and illness are often fused, generating damaged identity. In addition, traditional agrarian societies offer more normalization through flexible work roles and arranged marriages. In these societies, people with schizophrenia are five times more likely to marry than in the industrialized West (Hopper 2004). In developing countries, extended kinship networks relieve the burden often experienced by smaller households in developed countries. The nuclear family structure, with its limited capacity for caregiving, is related to high expressed emotion, which entails hostile criticism or emotional overinvolvement in some family members. High expressed emotion is correlated with patient relapse, but is less frequent in non-Western cultures and is largely remediable with family psychoeducation (Leff and Vaughn 1985).

In contrast to now discredited theories that implicated families in causation, a literature has emerged on the impact of schizophrenia on families. Research indicates that the families of people with schizophrenia face both objective burden, which include the time, energy, and
finances devoted to illness management, and subjective burden, which refers to the emotional costs of coping with difficult behaviors and the pain and losses of a loved one. Families have dealt with their distress by organizing into movements throughout the world to improve research and services and to combat stigma. People with schizophrenia suffer the terrors of psychosis, diminished life aspirations, and social devaluation. Social and cultural conceptions range from retribution for personal or ancestral misconduct to the split personality definition that has made the word schizophrenia an erroneous synonym for self-contradiction. Media accounts of violence reinforce societal stigma, although people with schizophrenia are more often victims than perpetrators.

In spite of these challenges, many deinstitutionalized patients are functioning well in their communities. Longitudinal studies in Europe and the United States show that more than half of formerly hospitalized, presumably chronic patients with schizophrenia can, with proper treatment, lead satisfying, relatively symptom-free lives. Studies of mostly first-episode patients show from 48 percent to 91 percent experiencing symptomatic remission posthospitalization (Liberman and Kopelowicz 2005). A burgeoning consumer movement of former patients, many with schizophrenia, offers peer services, recovered role models, and hope. With continuing research on improved medications, psychosocial interventions, peer services, and genetic predictors of more exact individualized treatments, the prognosis looks more favorable than ever before.

**SCHLIEMANN, HEINRICH 1822–1890**

Born in Neubukow in Mecklenburg-Schwerin, Germany, on January 6, 1822, the son of a Lutheran minister, Heinrich Schliemann received his secondary education in Neustrelitz and became a grocer’s apprentice (1836–1841). He took an intensive course in bookkeeping, but finding no suitable employment in Germany, he decided to sail to Colombia to make his fortune there. When the ship ran aground off the coast of Holland, he became a clerk with Schroeder’s, a large trading company in Amsterdam, and eventually their agent in St. Petersburg, where he also set up his own business and married Yekaterina Lyshin in 1852. The marriage produced three children but was not a happy one. Schliemann made a great deal of money buying and selling commodities on the St. Petersburg exchange. In 1868 he went on a grand tour through Italy and Greece to the Troad in Turkey, hiring workmen to make tentative excavations on Ithaca and at Pinarbashi (Troad). The British expatriate Frank Calvert, who had made small excavations at Hisarlik, convinced Schliemann that that was the site of Troy. Schliemann resolved to return and dig there. In 1869 he received a doctorate from the University of Rostock for his book *Ithaque, le Péloponnèse et Troie* (Ithaca, the Peloponnesus, and Troy), divorced his Russian wife in Indianapolis, and married Sophia Engastromenos in Athens. This marriage, which was almost as stormy as the first, produced two children.

After an exploratory (and illegal) dig in 1870, he began a campaign of excavations at Hisarlik (1871–1873) with a large number (70–100) of workmen. These revealed a series of nine superimposed settlements. Schliemann reckoned the second oldest of these (Troy II) to be Homeric Troy. This seemed to be confirmed in May 1873 when he found at that level a large hoard of metal objects including gold and silver vessels and jewelry, which he called “Priam’s Treasure.” Even more important were his excavations at Mycenae (1876). These brought to light an advanced civilization on mainland Greece that predated Periclean Athens by a thousand years. Before Schliemann, no one had dreamed of its existence. The finds in the shaft graves there were richer and far more sophisticated than those at Troy. Attempting to establish clear connections between Troy and Mycenae, Schliemann returned to excavate at Troy in 1878, 1879, 1882, and 1890. Finally, in 1890 conclusive proof emerged that Troy II was far earlier than the shaft grave burials at Mycenae, though Schliemann did not acknowledge this in his 1890 report. Subsequent excavation has shown that Homeric Troy should be dated to the last levels of Troy VI (according to Wilhelm Dörpfeld and recently the German-
American excavation team led by Manfred Kormann) or to Troy VII (according to Carl Blegen, who excavated Troy 1932–1938). Among the many other sites Schliemann excavated, Tiryns and Orchomenos are the most important. He died in Naples on December 26, 1890.

The accuracy of some of Schliemann’s archaeological reports has been questioned in recent years. It is now clear, for instance, that “Priam’s Treasure” is not a single find, as Schliemann claimed, but a composite of many pieces found over months of excavation. However, much of his work has been confirmed by his successors. He remains a crucial figure in Aegean archaeology.

SCHOOL VOUCHERS

The immediate purpose of school voucher programs is straightforward enough: they are designed to provide families with cash subsidies that help defray the costs of a private education. The larger social objectives that school voucher programs purport to serve, however, vary considerably. Some people promote vouchers on the grounds that they inject competitive forces into a monopolistic public education system. Others extol the perceived benefits of a religious education; namely the teaching of moral values, discipline, and prayer. To some they rescue students trapped in failing public schools, while still others suggest that vouchers are a civil rights issue, extending educational opportunities to predominantly poor, minority, and urban residents that heretofore have been the province of wealthier, whiter populations.

It is little surprise, then, that the specific features of actual voucher programs vary widely. A handful of programs are funded with taxpayer dollars, while numerous others are financed with private donations. Programs intermittently target students with disabilities, students attending chronically underperforming public schools, low-income families, or rural residents who lack ready access to a public school. The particular mix of participating secular and religious schools also varies from program to program, as do the specific requirements and accountability systems with which private schools must comply.

The first voucher experiment in the United States began in 1990 in the city of Milwaukee, where tuition subsidies of up to $2,500 were offered to low-income families. For the first eight years, the program could legally serve no more than 1.5 percent of the city’s public school population (approximately 1,700 students), and only secular schools were allowed to participate. In 1996 the state of Wisconsin permitted up to 15 percent of the Milwaukee public school population to participate in the program. The state also expanded the menu of private schooling options to include religious institutions, and it increased the monetary value of the vouchers. A lawsuit objecting to the expanded program’s constitutionality delayed its implementation until 1998, when the Wisconsin Supreme Court upheld the program. Since then, the numbers of private schools and students participating in the voucher program have expanded rapidly.

Other publicly funded voucher programs have been implemented in Cleveland, Ohio; Florida; and Washington, D.C. Ohio enacted a pilot voucher program starting in the 2006-2007 school year, and Vermont and Maine have voucher-like tuition programs that assist children residing in rural districts to attend either a secular private school or a public school in another district. In the 2005-2006 school year, roughly 14,200 non-special-education students participated in the voucher program in Milwaukee, while 5,700 did so in Cleveland, 733 in Florida, 1,090 in Washington, D.C., 5,450 in Vermont, and 6,250 in Maine. And thousands more beside have enrolled in privately funded voucher programs in such cities as Dayton, Ohio; Indianapolis, Indiana; San Antonio, Texas; and New York City, as well as a national program operated by the Children’s Scholarship Fund.
THE EFFECTS OF SCHOOL VOUCHERS

The origin of the modern voucher movement can be traced to the Nobel laureate Milton Friedman's defense of parental school choice in *The Role of Government in Education* (1955). Friedman promoted vouchers as a way to spark competition, improve the efficiency of public school systems, and improve the actual performance of schools. John Chubb and Terry Moe revived the idea in *Politics, Markets, and America's Schools* (1990), in which they explicated why private institutions have stronger incentives than public ones to mimic "best practices" in education.

In the early twenty-first century, a lively debate persists about whether the threat of losing students (and the dollars attached to them) to other districts or to private schools induces public schools to operate more efficiently. In one especially influential paper published in 2000, Caroline Hoxby found that competition among public school districts improves school productivity by simultaneously raising student achievement and lowering spending. Reanalyzing the same data, Jesse Rothstein came to very different conclusions, which Hoxby then refuted. In a separate exploration of the voucher programs in Milwaukee, Cleveland, and San Antonio, Frederick Hess carved out a middle ground, arguing in 2000 that competition induces only moderate productivity increases, unless the internal structure of the public school system sets performance-based incentives throughout the system.

Whether vouchers raise the performance of those students who use them has been equally controversial. In 1995, John Witte, Troy Sterr, and Christopher Thorn claimed that students who participated in the original, limited voucher program in Milwaukee scored no higher than a random sample of public school students and low-income students. Using the unsuccessful applicants as an alternative control group, Jay Greene and colleagues found in 1996 that the voucher program had a significant positive effect on the students' achievement in math and reading. Using yet another methodology, Cecilia Rouse concluded in 1998 that students participating in the program learned at a faster pace in math and at a similar pace in reading, compared to their peers in public schools.

Because families self-select into public and private school populations, it can be extraordinarily difficult to determine whether observed differences between them are due to the quality of the schools in the two sectors or the kinds of students who choose to attend them. The best evidence regarding vouchers, therefore, comes from randomized field trials, in which vouchers are assigned to an eligible population by means of a lottery. In several privately funded voucher programs in the United States, it was possible to conduct such analyses. After examining such programs in New York City, Washington, D.C., and Dayton, Ohio, William Howell and Paul Peterson found that vouchers had positive effects on African-Americans' test scores but no effect on those of white or Hispanic students. Additionally, as a result of using vouchers, parents did not appear any more or less involved in their children's educational lives; parental satisfaction with their children's schools improved substantially; and the probability that children attended religious services increased, though the frequency of church attendance among parents actually decreased.

Evaluations of voucher programs elsewhere in the world have been similarly mixed. In 2002, Angrist and colleagues found that Colombian students who were awarded vouchers repeated grades less often and achieved higher test scores. In a 2000 study, Edward Fiske and Helen Ladd offered no conclusions about the overall effect of New Zealand's parental choice system, but they argued that the system exacerbated the social stratification of the nation's school system. Both positive and negative effects on Chile's unrestricted voucher program have been reported. Chang-Tai Hsieh and Miguel Urquiola found no evidence that vouchers improved average educational outcomes, though they observed that the best public school students left for private schools as a result of the program. Francisco Gallego, meanwhile, found that the competition increased students' test scores in public and voucher schools alike.

THE POLITICS OF SCHOOL VOUCHERS

In 2002 the U.S. Supreme Court affirmed the constitutionality of the Cleveland voucher program in *Zelman v. Simmons-Harris*, rejecting the claim that the use of public funds to send children to religious schools violated the First Amendment's establishment clause. The Court found the program to be neutral with respect to religion because parents were allowed "to exercise genuine choice among options" that included religious and secular private school, magnet schools, charter schools, and traditional public schools.

Despite *Zelman*, controversy continues to plague voucher initiatives. Voucher programs have faced strong opposition from teachers unions, the existing public school establishment, and such advocacy groups as People for the American Way and the National Association for the Advancement of Colored People. Through legislative battles and lawsuits, these groups have effectively slowed the expansion of school voucher programs. Outside of Milwaukee, where tremendous growth has occurred, only about 7,500 more students around the nation used publicly funded vouchers in 2005 than in 1991. Though considerably more students have participated in privately
financed school voucher programs, topping out at over 100,000 in 2000 (Ladner 2001), enrollments over the last several years appear to have either leveled off or declined.

State judges are partially responsible for arresting the expansion of voucher programs. A pilot voucher program enacted in Colorado in 2003 never saw the light of the day because the state’s supreme court ruled that it violated the state constitution’s requirement that local districts maintain control of locally raised funds and of “any discretion over the character of instruction participating students will receive at district expense” (Owens v. Colorado Congress of Parents, 2004). In early 2006, school vouchers suffered another setback when the Florida Supreme Court struck down the state’s program in the name of educational “uniformity” in Holmes v. Bush. Other voucher programs have been defeated by voters. In November 2000, both California and Michigan voters rejected school-voucher ballot initiatives.

Public support for vouchers has proven difficult to gauge, not least because of survey respondents’ sensitivity to the wording of questions. In 2002, for instance, the annual Phi Delta Kappa/Gallup Poll asked for people’s opinion about vouchers in two different ways. A majority of respondents supported vouchers if asked one way but opposed them if asked another way. Since 2002 the Phi Delta Kappa/Gallup Poll has left out the more neutral of the two questions, which, incidentally, also yielded higher support for vouchers. Regardless of question wording, however, in 2001 Terry Moe found that low-income, black, and Hispanic residents in disadvantaged school districts constituted the strongest proponents of vouchers, while wealthy white suburban residents constituted the strongest opponents.

Among political elites, support for vouchers varies markedly across party lines. Republicans tend to favor them, championing the supposed power of unfettered markets and small government. Most Democrats, who have close ties to unions and a history of supporting public education, are skeptical of many forms of choice, especially vouchers. Indeed, congressional votes for the 2004 District of Columbia pilot voucher plan split along party lines. In the House, Republicans were 52 percentage points more likely than Democrats to support the plan, while in the Senate they were 42 percentage points more likely to do so.

Looking forward at the national level, school voucher programs face an obvious political challenge. Those political elites who are predisposed to support vouchers (Republicans) disproportionately represent constituents who oppose them (suburban whites), while those elites (Democrats) who represent strong proponents of vouchers (urban minorities) also have strong ties to teachers unions, which vigorously oppose them. Despite calls for a national voucher program, the expansion of voucher programs is likely to be the continued result of a combination of privately funded initiatives and an unusual alliance of younger African-American city leaders and Republican mayors and governors.

SCHOOLING

Around the world, organized education, or schooling as it is better known, has long been responsible for socializing members of society to adopt and practice its values and culture. For example, early schooling focused more on indoctrinating children into a collective religious, dynastic, or national identity rather than individual self-expression. From this standpoint, schooling sought to produce self-knowledge within educators so that they might help produce that knowledge in others. For nearly its entire existence, however, formal schooling has been highly selective in determining whom it educates and for what purpose. Until the advent of the Industrial Revolution, schooling was an activity relegated only to the elite members of a society, as its purpose was to perpetuate elitism and maintain class stratification.

Individuals were educated for careers in the clergy, military, government, and academia. In any given country, however, educated citizens made up only a small proportion of the population. The masses, if educated at all, simply learned through the transmission of information from family and other members of the community, as the elite classes did not believe educating the masses to be socially desirable or responsible (Gutek 1993). In the United Kingdom, for example, a majority of the population could neither read nor write until the early nineteenth century. This pattern of schooling remained consistent throughout much of the world until the Industrial Revolution.

With the Industrial Revolution, some societies found themselves in need of a new, educated middle class. Faced with the need to educate large populations, societies began to develop compulsory, state-supported schools. Because the population of citizens to be educated was growing, societies could no longer be as selective in determining who would be educated. As the number of students increased, they exhibited varying degrees of ability. As a result, schooling became a vehicle to sort students into various levels based on their abilities. Students believed to be able to profit most from schooling were tracked into more traditional paths, while those believed to be able to profit least were sorted into paths that led them out of the educational system. This practice of sorting students into different academic tracks, although now more sophisticated, has prevailed in education systems around the world.

As argued by scholars such as Michael Apple, Henri Giroux, Paulo Freire, and Joel Spring among others, there is an undeniable relationship between education, power, and the state. In light of the current globalization of schooling, academic success is almost exclusively defined in terms of “capital accumulation and the logic of the marketplace” (McLaren 2002, p. 34). Not only are working-class students affected by this principle, but middle-class students are as well. American culture, for example, continuously encourages the consumption of commodities as a mechanism to continue the cycle of accumulation, blinding even middle-class students to the self-repressive, oppressive nature of capitalism. The schools mimic this cycle by intellectual dependence in students (Gatto 1992). The focus of educational reform in the United States has been to create a force of “compliant, productive and patriotic workers for a resurgent America” (McLaren 2002, p. 187). Schools, with their factory-like structure, control the process of learning by keeping students on tight schedules regulated by bells and time blocks. Learning, therefore, is at the mercy of the school’s schedule, and students learn only what can be taught in the allotted time span. Learning is prescribed by the society, and students are told what to learn, when to learn it, and how (Gatto 1992). Looking at this phenomenon from a Marxist perspective, capitalism diminishes the individual to a commodity with a certain value—labour value—that can be bought and sold all in the name of profit. In essence the ruling class (the capitalists) exploit the working class (the workers) by extracting “a surplus value beyond what is necessary for the working class to survive” (McLaren 2002, p. 198).

Teachers are also prescribed what and how to teach. Many teachers fear losing their jobs if they deviate from the curriculum that society has deemed appropriate for them to follow. From a critical educational standpoint, schooling is a “form of power which reveals its connections to the entrenched interests of capital and the state, exercised ‘over the heads of teachers’ and through teachers over their students” (Banya 2002). This is evident in the push toward incorporating corporate management pedagogies within the classroom. Teachers are provided...
“teacher-proof” state-mandated curricula that adopt management-type pedagogies that reduce their role to that of nothing more than a “semi-skilled, low-paid clerk” (McLaren 2002). Furthermore, they are “unwitting pawns in class and cultural domination and exploitation” (McLaren 2002, p. 221).

Society, through schools, teaches us that success can be achieved by intelligence, hard work, and creativity. The school system is built on the spirit of meritocracy—those students who try harder and have more innate intelligence reap their rightful rewards. Students who possess the dominant cultural capital—ways of talking, acting, and socializing—are rewarded, while those possessing the cultural capital of the oppressed are devalued. As a result, schools perpetuate the unjust system of trading in cultural capital for economic capital.

Educational inequality is a persistent problem, particularly in terms of race, gender, and social class. In the United States, for example, women and minorities have historically been limited by and excluded from attaining higher levels of education by discriminatory policies. There are those, however, who argue that “things should be different now” because of the opportunities in the public and private sectors available to those who have a good education.

In terms of race, a growing black middle class has raised new concerns regarding the lagging school performance of many African Americans. The new argument is that “class” and not “race” are the root causes of inequality in America. As middle-class African Americans leave urban, inner-city areas, the largely manufacturing employment sector also leaves, thus creating an “under-class” of citizens who are left behind to endure the brunt of poverty and inequality. Poverty is a major barrier to quality education, as many schools in lower income communities have curricula designed to keep poor people in their place (Spring 1989).

In terms of gender, teachers are more likely to value the opinions of middle-class white male students over those of females (McLaren 2002). Girls, for example, are expected to be composed and passive, while boys are encouraged to be more academically aggressive. As a result, girls are less likely to take math and science courses, more likely to attribute failure to internal factors, and although they start school ahead of boys in reading and math, they graduate from high school with lower scores in both areas.

These practices are not perpetuated by force, however. The dominant culture, rather, is able to exercise power over subordinate classes through hegemony—the maintenance of domination through consensual social practices, social forms, and social structures (McLaren 2002). Students are not taught to question the prevailing capitalist values of the nation, and as a result, the culture has helped produce a “veritable passion for ignorance” (McLaren 2002, p. 217). And the social structures—the church, the schools, the mass media and the family—have all been shaped by the dialectical contradiction between labor and capital.

This marketization of schooling is not solely a Western phenomenon. Educational systems in many West African countries were initially developed in the image of Western-type educational systems during the late 1800s and early 1900s in response to perceived needs of the colonizers (Banya 2006). Schools were established for a variety of reasons—commercial, religious, and political—but rarely were they established for indigenous needs. Initially, Christian churches played a major role in the development of educational facilities, and later trading companies and local colonial governments eventually provided their own (Banya 2006).

The major aims of the school systems were to provide personnel for the activities of government administration, the church, and commerce. In attempting to achieve these aims, the frame of reference was entirely Western. In most countries the systems were elitist, focusing their resources and attention on the students who could successfully negotiate the system and take their place in the colonial structure that was being established. As in Western education, West African schools have the responsibility of socializing students to the values and customs of the society. Primary education, for example, introduces those fundamentals necessary to produce an individual who, at a basic level, is able to contribute meaningfully to life in his or her community. Furthermore, the goals of junior and senior secondary level education are the continued acquisition of basic skills and knowledge and the introduction of subjects encouraging the development of nationally desired and saleable skills. Schooling in this sense is designed to utilize each individual's ability, aptitude and interest to equip individuals with skills to satisfy society's manpower needs. They are also expected to develop a character that would help cultivate desirable attitudes and regard for the nation's well-being (Banya 2006).

While the argument can be made that the function of schooling is to prepare citizens to effectively participate in a global economy, it is also important to understand its role in creating autonomous, independent thinkers. To date, however, educational systems continue to perpetuate inequity and injustice.

SCHOOLING IN THE USA

The ancient Greeks believed that education was the optimal means for transmitting and reinforcing societal values through the generations. They believed that religious life should coexist with public life (e.g., society and the state) so that society might flourish by sustaining the prevailing culture's norms and values. For this process to occur, the young must be trained and educated and their character shaped.

COLONIAL EDUCATION

Many U.S. founders adopted a similar theory of education, believing that the republic would not survive without sufficiently educated citizens. For the founders' ideas to thrive, appropriate policies were needed to drive the process of educating young citizens in God and country. The importance of public education and the policies that drive its function have transformed and continuously shaped the identity of the United States since its inception, creating an often turbulent history. Many of the founders of American education focused on education as vital to the continual progression of the republic and, in particular, white Protestant morals. The U.S. educational system and the policies enacted were for white males, by white males, for the purpose of advocating their economic, social, and political interests. After much resistance, women were later granted admission to education, and blacks were the last minority group to gain access.

The linkage between public life and education in the United States was not immediate (Salomone 2000). Seventeenth-century colonists did not believe that religion and public life should coexist. In fact, the founders instituted a separation of church and state. As a result, schools were used primarily to reinforce the religious beliefs of the prevailing white citizenry. Since the colonists' main financial resource was agriculture, education was less critical to the economy. Schooling took place primarily within the home, as the burden of teaching children was laid upon the family unit and the white Protestant church. The few schools that existed at the time were seen as short-term places of learning. Many were held for just ten to twelve weeks out of the year, favored boys, and were substantially influenced by wealthy landowners and the Protestant perspective. Early schools also charged fees, which helped to stretch the minuscule monies spent by towns. Before the American Revolution, "education was neither free nor public" (Kaestle 2001, p. 20). Indeed, a family's race, wealth, and social status heavily impacted the amount of education their children received and their potential outcomes.

THE COMMON SCHOOL

Following the American Revolution, influential men such as Thomas Jefferson, Noah Webster, and Benjamin Rush became concerned at the lack of school expansion and the uneven distribution of education. They advocated statewide education that would be systematically supervised. During the 1790s, Jefferson and Rush made failed attempts to legislate state systems of education in Virginia and Pennsylvania. But with the help of Horace Mann, the first secretary of education for Massachusetts, the idea of a statewide school system finally took hold. Mann devised the "Common School," which replaced the colonial mode of education. These schools would impart a higher quality of education for both boys and girls, giving them a chance for a good life while ensuring the survival of the republic. He proposed that schooling should be free and thus be equally accessible to all, thereby increasing the social capital of all, regardless of social position in life, and enhancing democracy. Mann understood that children of higher social status who could attend school had an advantage because of the cultural capital of belonging to a high-status family with high academic expectations. Following Mann's common schooling initiative, education was to put all children, regardless of cultural capital, on an equal footing. Schools would be headed by women, who many felt were dispositionally designed by God to be the principal educators for the white race. Many young women headed west not only to teach the three R's but also to instill discipline and promote national ideals. The common school became the new direction and principal version of public education throughout the United States.

This approach did not proceed without major conflicts between political parties, such as the Jacksonian
Democrats and the Whigs, who debated the role of the government in school expansion and policies. Resistance to centralized state mandates and government intervention also took place in local communities around the country. But Mann persisted in his fight to end the inequalities of the colonial educational system, and in 1860 state laws were established instituting government control. Finally, schools would be funded by taxes and follow state standards.

THE INDUSTRIAL REVOLUTION AND BEYOND

The purpose of common schools shifted again as a result of the Industrial Revolution and the concomitant increase in immigration. Most white Americans were concerned about the new immigrants, regarding them as poor, socially and morally deviant, and threatening to the predominant white Protestant way of life. Schooling became a critical device for assimilating new immigrants to the ideas of Protestant morals, respect for private property and authority, hard work, patriotism, and accepting one's given second-class citizenship in the social hierarchy, while at the same time training them to understand the political and public affairs that were important to expanding America through the world economy.

The nineteenth century ended with many changes in education and a vast expansion of American schools. Many scholars have noted that the changes in education and educational policy were closely connected to U.S. economic needs (e.g., Vinovskis 1999). The practice of holding school for children until the eighth grade changed because of the new skills demanded of workers. Children were being asked to stay in school longer than they had in previous decades. Later, secondary education was added. In addition, rising curriculum standards, an increased teachers' knowledge base, and additional state and federal control forced the creation of stricter education policies that standardized the practice of education.

Because of government and business influences, education policy transitioned from the philosophy that the role of schools was to provide moral teaching to the philosophy that their role was to provide vocational and industrial education. After World War I, group intelligence tests were used to place children on curricular tracks that purported to demonstrate differences among immigrants, racial minorities, and whites. In the end, the purpose was to show the country that immigration should be restricted. Some proponents of IQ tests felt that they could also be used to assign groups of children to tracks that allegedly offered education that benefited their individual needs. But many saw the educational policies that drove these tests as not simply assigning children to appropriate vocational or academic tracks but as a form of social engineering that restricted the opportunities of immigrants and other minorities.

By the 1950s, many government officials were coming to believe that schools suffered from lower standards that enabled such countries as the Soviet Union to beat the United States in the space race. In response, policy initiatives such as the National Education Defense Act of 1958 provided funding for graduate students to study foreign languages, mathematics, and other sciences. Later, “education, as a form of investment in human capital, was recognized as an important component of economic development in the 1960s” (Vinovskis 1999, p. 153). In decades to come, education policy would be used to provide for the growth of schooling to stimulate economic expansion. This idea of viewing children as human capital was renewed in the 1980s and 1990s and continues in the twenty-first century.

THE CONTEMPORARY SCENE

Although in contemporary America schooling is believed to be universal and connected to the founders’ purpose, discussion surrounding public education is more complicated today than ever. Many groups are attempting to reform public education through a variety of initiatives, and many of the same past issues have reemerged. The actors in these conflicts include politicians, administrators, boards of education, special-interest groups, teachers unions, corporations, and foundations. Many functionalists argue that public education and policy have triumphed because education has stayed true to the founders’ ideals in continuing the success of the republic. Functionalists accept social inequality as necessary, arguing that social inequality encourages competition, which pushes people to perform to the best of their abilities to attain a desired social level. Therefore, individuals and minority groups without power are in constant conflict, always striving for a better place on the social hierarchy. These theorists believe that an individual or a group’s social mobility is determined by their own efforts because everyone, regardless of race or gender, has equal access to education and resources.

Both the Reagan and Bush administrations of the 1980s and 1990s closely adhered to this functionalist doctrine, favoring political approaches to social issues that affected the poor and minority groups. Under the functionalist paradigm, individuals are to blame for their own lack of resources, power, and education. Both administrations blamed the educational system for the failure of public education. The 1980s reports A Nation at Risk and Action for Excellence blamed public education for the nation’s decreased status in the global markets. With Richard Herrnstein and Charles Murray’s 1994 book The Bell Curve, attention was redirected to children, especially...
the supposed deficiency of minority and lower-class children, who were blamed for the nation’s drop in competitiveness in global markets.

This approach again became prevalent in the George W. Bush administration through policies and legislation such as No Child Left Behind. Supporters of the policy argue that the education reform act “is aimed at addressing the needs of disadvantaged children, closing the gap between the rich and poor kids, improving accountability, and offering schools more financial resources to improve their performance” (Giroux 2003, p. 72). Parents can obtain vouchers to choose and pay for education that fits their child’s needs if their current school is not achieving government standards within three years. Many voters agreed with Bush, voting largely for a presidential candidate who ran on a strong market-based approach to education policy. This market approach is also seen in the concept of charter schools, which first emerged in 1992 in Minnesota as advocates demanded change in urban schools. Proponents of charter schools see them as a way of enhancing competition in public education by focusing on student achievement while at the same time empowering parents with choice. Opponents such as Jonathan Kozol (1992) note that “choice will fragmentize ambition, so that the individual parent will be forced to claw and scramble for the good of her kid and her kid only, at whatever cost to everybody else” (p. 92). But in reality, the market approach and legislation such as No Child Left Behind focus on the academic and social deficits of poor and minority children and not on the structural deficits of the economic and educational institutions. The blaming tactic that focuses on the low achievement of poor and minority children as well as the operation of public schools takes attention away from economic issues that are closely connected to student achievement. It has also galvanized the connection of the corporate world with public education by treating schools as if they were businesses within the marketplace.

RACE, CLASS, AND EDUCATION

Conflict theorists have attempted to deconstruct the functionalist doctrine. They charge that every society operates socially and economically on the grounds of inequality that privileges the wealthy and powerful while attempting to convince lower groups that the gap in power, resources, or education are necessary to the survival of the society. Conflict theorists argue that schools are set up as mechanisms to sort and control minorities in an unequal manner, inhibiting their social mobility. In essence, regardless of effort, some children in U.S. public schools are set up to “lose.”

Conflict theorists consider the current schooling issues as a prime example of the inequalities that exist in public education. Miron (1996) states that in a study of an urban school setting in Louisiana, black students articulated a general dislike for the way school officials treated them. Miron asserts that the curriculum was used as a tool to discriminate against black students. In terms of observed behavior and academic practices, whites were found to be subjected to less rigorous observation than black students.

Secondly, despite significant progress during the civil rights era, some scholars today feel that the spirit of “true” integration never occurred in U.S. public schools. In fact, many feel that public schools today have shown signs of de facto segregation where by choice whites are increasingly leaving ethnically diverse inner-city schools for more homogeneous white surroundings in suburbs (Bell 2004; Kozol 2005). This becomes all the more believable when one recalls that the foundation of U.S. public education meant that whites would benefit from a white system of control.

African Americans have a particularly long history of denied and suppressed educational opportunities. For example, in the South, the expansion of the rights, privileges, and access to formally all-white institutions for blacks took place during Reconstruction (1866–1877). Blacks participated and successfully held governmental positions of power, voted in elections, owned land, partook in the economy, and sought education that was once denied to them during the era of slavery. Moreover, the Reconstruction legislation that affected public schooling in the South was the result of the important and influential efforts of ex-slaves not only to shape but also to create a catalyst for an established public school system for all children, which continues to exist in the South today. Ex-slaves’ desire for schooling was felt by old and young alike. Blacks at the time believed that obtaining an education enabled them to open the doors to democratic politics in the United States. In order to obtain an education, they appealed to federal and state governments.

Ex-slaves’ desire for education was founded on “self-help.” Even though blacks held together in securing a decent amount of resources on their own, blacks also knew they needed the assistance of outside white investors, as well as state and federal government funding, physical protection, and legislation that granted equality. Because of this need for assistance, blacks met many obstacles: lack of money, conflicts with northern white missionaries who tried to control the education process, community conflicts, and acts of terrorism. In terms of education, because of the protection of the Thirteenth, Fourteenth, and Fifteenth Amendments and the Civil Rights Acts of 1868 and 1875, blacks for a while enjoyed equal access to education. But this period of radical progressiveness and alliances between whites and blacks did
not last long because of such factors as the withdrawal of Northern troops from the South, the ousting of blacks from the Republican Party, physical and emotional terrorism by the Ku Klux Klan, and the Democratic Party’s return to political power. The U.S. Supreme Court ruling in *Plessy v. Ferguson* (1896) marked the collapse of Reconstruction by making it constitutionally legal to segregate blacks from whites as long as “equality” existed in their separation.

Two race “worlds” took root within the first decade of the twentieth century (Bell 2004). This was no more evident than in public education, with white and black schools. By separating whites from blacks, the process of schooling was another institutional example of the continuation of racial oppression of blacks. This unequal treatment was observed in the lack of adequate pay for school staff, inferior facilities, and lack of suitable academic resources in black schools compared to white schools. Even in the face of school segregation and considerably unequal financial resources—despite *Plessy’s* “separate-but-equal” clause—many black schools thrived because of the adoption of a “counterhegemonic” theme, meaning that they were “organized in opposition to the dominant ideology of white supremacy and Black intellectual inferiority” in order to create literate, academically achieving citizens and leaders who would continue the racial uplift of African Americans (Perry, Steele, and Hilliard 2003, p. 91). W. E. B. Du Bois in *Black Reconstruction* discussed how these schools did not exist in the South without the initiatives of blacks. Shortly after the Civil War, newly elected black officials and their collaborative efforts with the Freedman’s Bureau, aid societies, and missionary groups all helped to establish the first state-financed public education system for young and old blacks alike. During Reconstruction, many free blacks began to educate themselves and others. Black women soon filled an important role in establishing and maintaining the schools. These new facilities helped blacks become literate and empowered in the business, economic, and judicial worlds that were foreign to them. Schools provided a place for blacks to be educated on the agenda of the Republican Party, their rights as free blacks, and the importance of voting.

The legal segregation of public schools continued until *Brown v. Board of Education* (1954). In terms of Native Americans, they too were required to attend segregated government schools where they were forced to abandon their tribal traditions, dress, appearance, and customs, in an effort to assimilate them into white customs.

Educational policies and schooling have adapted to the dramatic changes in population, the economy, the push for racial equality, technological advances, war, and cultural transformation. What has remained constant is that elite whites who control power and resources continue to vie for power through policies, including educational policies that have been historically devised to maintain the status quo by denying equal access to education for all citizens. The foundation of inequality set in place by the founders is alive and present in today’s education system.

**BIBLIOGRAPHY**

Schumpeter, Joseph Alois
1883–1950

Joseph Alois Schumpeter was born in Triesch, Moravia (now the Czech Republic), on February 8, 1883, an only child of a textile manufacturer. After his father's premature death his mother married a high-ranking officer in the Austro-Hungarian army. Young Schumpeter enjoyed a typically aristocratic education—strong on the humanities, weak on mathematics and science—at the Theresianum in Vienna.

As a law student at the University of Vienna Schumpeter took courses in economics from Friedrich von Wieser (1851–1926) and participated in Eugen Böhm von Bawerk’s (1851–1914) seminars, joining other budding economists such as Ludwig von Mises (1881–1973) and Austro-Marxists Otto Bauer (1881–1938) and Rudolf Hilferding (1877–1941). He received his doctorate in 1906 and published his first book, Das Wesen und der Hauptinhalt der theoretischen Nationalökonomie (1908; still untranslated), a methodological treatise on economic theory. In 1909 he was offered a position as an associate professor in Czernowitz, capital of the southeastern crownland of the Austro-Hungarian Empire (now in Ukraine). In 1911 he was appointed to the chair of political economy at the University of Graz. By the outbreak of World War I he had already established an international reputation as an economist of the first rank: at the age of thirty he was awarded an honorary degree by Columbia University.

After unsuccessful excursions into politics and banking following World War I—he had served as secretary of state for finance for seven months in 1919 in the new republican Austrian government, and in 1921 he assumed directorship of the Biedermann Bank in Vienna—he returned to academia for good in 1925 as professor of public finance at the University of Bonn in Germany.

His sojourn in Bonn was overshadowed by the deaths of his beloved second wife and shortly afterward of his mother, blows from which he never recovered. Schumpeter's permanent tenure at Harvard University began on September 1, 1932, and he was connected with the university continuously, except for two sabbatical leaves, until his death on January 8, 1950. Schumpeter was a founding member of the Econometric Society, and served as its president from 1937 to 1941. In 1948 he was elected, as the first European, president of the American Economic Association.

Schumpeter was an encyclopedic scholar, equally versed in history, sociology, and economics, with a stupendous knowledge in the history of economic thought. More than any other economist before him, with the possible exception of German social philosopher Karl Marx (1818–1883), Schumpeter highlighted the role of innovation for the performance of market capitalism. By innovation he meant the introduction of new production technologies and new goods, the conquest of a new supply of raw materials, the setting up of new organizations of industries, and the opening up of new markets. For Schumpeter entrepreneurial action conceived as innovation is the central feature of capitalism, and it forms the backdrop to his theories of credit, interest, capital, profit, and the business cycle. In Schumpeter's scheme the entrepreneur as an agent of innovative change is a revolutionary, overturning tried and tested ways, departing from routine, resisting inertia, and producing novelty by putting extant resources to new uses. The carrying out of new combinations in production is the essence of “creative destruction,” a task accomplished by entrepreneurs.

Such bold and confident ways represent a distinct economic function. It is distinct from that of the inventor, the imitator, the capitalist, the banker, the manager, the landowner, and the worker. The entrepreneur may be any or all of these things, but if so it would be by coincidence rather than by nature of function. Neither is the entrepreneurial function necessarily tied to possession of wealth although it may be helpful, nor do entrepreneurs form a class in a sociological sense. It is not money per se that motivates entrepreneurs but rather the dream to found a private empire and the joy of getting things done against the odds.
The results of the entrepreneurially fueled innovation process being inherently uncertain, it is refractory to reduce them to mere calculation. The knowledge buttressing innovation need not be new, it is usually available knowledge that has not been deployed before at all, or else it is utilized in new ways. According to Schumpeter innovation is above all an act of will, depending on leadership, and should not be confused with scientific (or otherwise) invention. Schumpeter broke with tradition by denying that profit is a return to risk. Schumpeter argued that risk falls on the capitalist, not on the entrepreneur as entrepreneur, the latter as such being bereft of capital.

Schumpeter’s final great work published during his lifetime, Capitalism, Socialism, and Democracy (1942), focused on sociological aspects of capitalism, in particular the institutional structure of capitalist society. The paradoxical message emanating from his most popular book is that capitalism is doomed, not by its economic failure (as Marx averred) but by its success. Writing in the early 1940s, Schumpeter pointed to concrete tendencies within advanced capitalist society that he perceived as depleting its moral capital. He singled out the resentment capitalism breeds among intellectuals. According to Schumpeter capitalism had been disfigured by various historical tendencies to such an extent that it should really be called “socialism.” The transformations included the growth of interventionist governments, the advent of a managerial bureaucracy within both the public and private sectors, and the rise of a professional middle class with a mind-set completely at odds with that of the classic capitalist. These developments had been accelerated by economic depression and war. According to Schumpeter, socialism is merely the acknowledgment that they have taken place.

Among economists Schumpeter has been interpreted (rightly or wrongly) as saying that with the advent of large corporations and their generously funded research and development departments entrepreneurship and innovation would become increasingly routinized. The withering away of entrepreneurship would amount to innovation being reduced to a decision-making process amenable to rational calculation. This is precisely how the Soviet economy and its Eastern European satellites had set up their innovation systems (with disastrous consequences), on the assumption that innovation, being mere routine business, is plannable. Such a rationalistic approach to the innovation process would be incompatible with capitalist institutions.

In recent decades Schumpeter’s ideas on capitalism as “a method of evolutionary change” have instigated a renaissance in research on technological change led by economists, such as Richard N. Nelson and Sidney G. Winter (1982), favoring an evolutionary approach to economics.

Indeed Schumpeterian economics is one of the main sources of evolutionary economics.

SCIENCE

The term science (in Latin scientia, in Greek ἕπιστήμη) means “knowledge.” In philosophy it refers strictly to proven ideas, to the exclusion of hypotheses or speculations. Until the twentieth century, proof remained mysterious, but what it achieves has been clear since antiquity: certainty, truth unshakable by criticism or doubt. In the nineteenth century Newtonian mechanics was admitted as scientific in this strict sense, and its overthrow was an earthquake. Scholars now agree that certitude is limited to logic and mathematics. Thus scientists have shifted their efforts toward securing for science a surrogate certainty—usually probability.
This shift raises many new questions, thus far unstudied. For example, is Isaac Newton’s theory still scientific? In 1962 the historian of science Thomas S. Kuhn spoke of “pre-science” and of “petrified science.” Which defunct theory should remain in the up-to-date science textbook? Kuhn suggested that it should present only the latest ideas. Which ones? If not proof, what makes an idea scientific? This is one version of the problem of the demarcation of science (as sets of statements) in disregard for other aspects of the scientific enterprise and its context—intellectual, educational, sociopolitical, and so on. Another possible point of departure is the social dimension of science. In the early seventeenth century the English philosopher Francis Bacon said that the advancement of science would improve the human condition, so investing efforts in scientific research would be the most efficient way to spend one’s spare time. Georg Wilhelm Friedrich Hegel, the early-nineteenth-century German philosopher, noted that the invention of gunpowder made city walls useless and so altered the political landscape. The German political philosopher Karl Marx in the nineteenth century equated science with technology (grasso modo) and declared all social and political changes as due to technological progress. Following on Marx, in 1939 the English physicist J. D. Bernal made the dubious claim that medieval science was superior to ancient science. In 1964 the Marxist philosopher Louis Althusser rejected many of Marx’s sweeping generalizations but still declared the humanities mostly errors that express bourgeois ideology; he contrasted this ideology with science proper, which includes both the exact sciences and revolutionary dialectical materialism as he understood it. He did not trouble himself to demarcate these fields sufficiently to invite detailed discussions as to whether a certain theory, say, in physics or in economics, is or is not scientific. In 1919—decades before Althusser—the American economist Thorstein Veblen studied the nature of science in an effort to examine the validity of claims for the scientific status of diverse economic theories, including that of Marx. He demarcated science historically, by reference to the scientific ethos that, he said, these theories represent; this ethos is often called humanism, the same ethos that Althusser later dismissed as bourgeois. Veblen also drew attention to the wealth of empirical finds and role of theories as explanatory (as opposed to classificatory).

Twentieth-century social science developed ideas about specific aspects of society, including prestige—social prestige, the prestige of ideas, and the prestige of scientific ideas. (Prestige is enhanced by power over life; thus nuclear physics is most prestigious.) The concept of science must include the gathering of some sort of empirical information and the search for some interconnections between that information and certain ideas. Science then appears to involve intellectual activities of some sort. Already four centuries ago Bacon deemed science the outcome of the indiscriminate collection of factual information and its use as a solid foundation on which to construct truly scientific ideas. His view, perhaps modified, prevails as the myth of science. (Being a myth proper, it is used at times in its original variant and at other times in modification.) The problem of demarcation then becomes: What do I know, and how can I show that I truly know it? This approach puts science in a psychological context, raising the question, as suggested by the twentieth-century philosopher of science Karl Popper: Is the psychology used to characterize science scientific? Science is also a publicly available fund of knowledge; the traditional view of it as psychological leads to the view (characteristic of the approaches known as reductionism and psychologism) of everything social as inherently psychological.

If science can be viewed as psychological, so too can mathematics, as suggested by Bacon and the nineteenth-century English philosopher and economist John Stuart Mill. The refutation of this notion led to the revolutionary shift of the view of knowledge from psychology to sociology—from my knowledge to ours—opening the way for the study of the enterprise of science, its prestige, and the social class of its practitioners. This in turn opens interesting secondary questions: Are the teaching of science and the administration of science scientific? (Is the dean of the faculty of science a scientist?) Is all science-based technology scientific? The sociology of science, a young discipline hatched in the early twentieth century, has not yet reached these questions. Such questions pose a difficulty: Science is international, but science-based professions are not. (Compare Japanese science with Japanese technology.) Come to think of it, how international is science? (Is establishing some lingua franca for science advisable?)

Here is a general dispute about all human studies: Existentialists and postmodernists want them to be utterly context dependent, case by case; positivists and analysts want them utterly context free. Seeking a middle ground in sociological laws to set limits on fragmentation, one may view social institutions as generalizations that determine the extent of context dependence. Money is one such institution. Rather than speak separately of the interests of every economic agent, we speak of their profit motive, which, as Georg Simmel argued in 1900, is an intermediary. This role of money makes it important and explains the success of the economic theory that eliminates it from its equations (by replacing prices with relative prices). The trouble is, while waiting for sociology to develop, how should social scientists proceed? They can make use of trivial sociology that at times is powerful. The suitable general concept here is that of games or science regulated by recognized rules (usually institutionalized).
Games need not be problematic unless placed under the artificial limitations imposed in game theory, and as in the case of war games, they need not always be frivolous. As to the triviality of the sociology of games, it is advantageous: It stops the question-begging nature of the theory of science from becoming a nuisance. Thus the rules of the game are negotiable. The game of science then might, but need not, exclude science administration, science education, (science-based) technology, and more. Also the rules may be flexible. All this is a secondary issue, as it obviously should be, as long as science remains chiefly the search for ideas and information of a certain kind. The problem of demarcation now reappears: Which kind? Any kind we want.

As this view of science allows excessive freedom, it also invites instituting limitations—to some function, to some tradition, or to some existing paradigms. Paradigms can be ideas (Newton on gravity), preferred ideas (Einstein), institutions (the Royal Society of London, the local medical school, the patent office), traditions, perhaps ways of life. Approaches to problems via paradigms are limited: Taken too seriously, they prove troublesome as too much may depend on an innocent arbitrary choice. The paradigm of this trouble concerns choices of words resting on the view that the commonness of usage is its only justification. We do not want all usage justified, because we want language to function as a useful means for communication.

What then is the function of science? Among several functions, its most conspicuous is explanation, discovery, invention, better living. Jumping a few steps ahead, one can say that its chief function is the search for true explanations (as suggested by Newton, Einstein, and Popper). Its other functions are peripheral. Assuming this to be the case, one can view science as primarily but not solely the enterprise of approaching true explanations of increasing funds of publicly available information.

This is lovely but full of holes. How do we learn from experience? In what way are scientific theories empirical? Popper broke new ground when he said that theories are empirical when they exclude certain observations and to the extent that they do so. Testing them is, then, the search for these observations; the function of testing theories is to refute them so as to usher in their successors. Applying such a test to the theories of Marx and Sigmund Freud, Popper proved them nonempirical. This approach depends on the exact wording of theories, which may become testable by the enrichment of their contents. Popper later tried to square the two ideas: that the empirical is the refutable and that the aim of theorizing is the approximation of the truth (Einstein). The success of his attempt is under debate.

Robert K. Merton approached matters more historically. In 1938, in the wake of Max Weber, the German sociologist of the late nineteenth century and early twentieth century, Merton identified the scientific revolution with the establishment of the Royal Society of London and the motive for it as Protestantism. He then developed a quasi-Weberian model of science, resting on the theory of science of William Whewell (1840, 1858). Merton’s views earned much fame and much criticism. The criticism is at times valid, as Whewell’s view is outdated, and at times based on trivial evidence that he idealized science (which he frankly admitted), both in the sense of presenting it at its best and in the sense that Weber recommended the developing of an ideal type. Reports on poor examples of laboratory life as if they were representative appeared as alleged refutations of his views, although fraud is hard to eradicate anywhere.

The presentation of science by Michael Polanyi (1958, 1966) is the most intriguing, even though he played down the rationality of science. He compared the sociology of science to that of the arts and deemed both artistic and scientific training as the tacit transmission of ways of life in workshops by way of personal example. Polanyi’s view is insightful and beneficial, although it overemphasizes tradition as endorsement while slighting the traditional encouragement of criticism and of independence (as suggested by Popper). Polanyi was in error when he ignored efforts to render the tacit explicit and open the results to criticism.

Polanyi’s views were further developed by Kuhn, who wished to extend the instruction of leaders beyond their immediate personal example limited to their workshops. Their products can travel and serve as substitutes for personal examples. These become chief examples or, in Greek, paradigms. A science is mature, he said, as it gains paradigms. He also admitted that identifying a paradigm is difficult. This difficulty should not trouble followers of Polanyi, but it does bother followers of Kuhn, as he declared paradigms obligatory. Kuhn’s approach runs contrary to the view of Merton about the liberalism of science. Kuhn also declared his theory applicable only to the study of nature, not of society.

How do the studies of nature and society differ? Any discussion of this question has to be in accord with one view of science or another. One may of course go to and fro, using the best view of science to differentiate natural and social science and then taking the best differentiation one has to try to learn what it says about science. One thing is certain: Social sciences have a more important role
to play in the discussion of science than was heretofore believed.

SCIENCE FICTION

Science fiction consists of stories, often set in the future and off the planet Earth, that emphasize scientific, sociological, and especially technological innovation. While a writer might imagine what could happen to, say, an Irish Catholic politician who felt attracted to his brother’s American Episcopalian wife in the 1960s, a science fiction writer might imagine what could happen to an implant formed from the mental software of a human male and the hardware body and brain of a human female. Similarly, while Henry James (1843–1916), in Daisy Miller (1878), imagines a nineteenth-century American heiress involved with a European suitor, the science fiction writer Ursula K. Le Guin, in The Left Hand of Darkness (1969), speculates about a human male who comes to know a hermaphrodite humanoid, a Gethenian, who sometimes turns male or sometimes female, depending on its emotional circumstances (the Gethenian often remains neuter if no suitable partner is around). James concentrated his attention on Daisy Miller, her commanding father, her suitor, and so forth, while taking the social, cultural, and biological background for granted. Le Guin, in contrast, imagined a world without gender and in conse-
quence (or she so thought) without war, examining it through the eyes of her human visitor.

Science fiction has been said to begin with Mary Shelley's *Frankenstein* (1818) or with Jules Verne's *From the Earth to the Moon* (1865) and *Twenty Thousand Leagues under the Sea* (1870) or even as far back as Plato's *Timeaus* (c. 300 BCE), his imagined version of Atlantis. However, science fiction as a distinct literary genre, with specialty magazines such as *Amazing Science Fiction* and *Astounding Science Fiction*, dates from the late 1920s and early 1930s. Its “golden age” of the 1950s and 1960s was driven primarily by technological speculations about the future, whether set primarily on Earth or spreading throughout the galaxy (with science fiction heroes typically confronted by rapacious aliens). Early readers of science fiction were often budding engineers and natural scientists. Writers and characters were mostly male. Isaac Asimov (1920–1992), although he began publishing science fiction stories in his teens, became a professor of biochemistry at Boston University, eventually publishing over five hundred books. (He was fired from his tenured professorship, not for writing science fiction but for publishing factual science texts for the general reader—“popularizations”). Many of Asimov’s stories concerned robot-human interactions. His Foundation series sketched the psychohistory of a vast galactic civilization, loosely paralleling the decline of the Roman Empire and the rise of the modern era.

Robert Heinlein (1907–1988) and Fritz Leiber (1910–1992) created theories of time travel that have fascinated philosophers and physicists (e.g., if you kill a butterfly in the age of dinosaurs, will this event cascade into a future in which intelligent dolphins dominate the world, or will the future conserve reality by resisting change?). In *Gather, Darkness!* (1943), Leiber anticipated a post–World War III dark age of theocracy in which a religious government maintains control using technology concealed as supposed miracles, only to be challenged by revolutionary forces that clothe their technology as witchcraft, thus making it real to the thoroughly medieval mind-set of the populace. Heinlein produced a version of Plato’s *Republic*, titled *Space Cadet* (1948), in which he imagined a future where an intelligent elite has engineered a world government that the populace believes to be a democracy. Later, during a period of opposition to the U.S. war against Vietnam (1957–1975), the patriotic Heinlein lost trust in intellectuals and wrote *Starship Troopers* (1959), in which warriors ruled politically. Paradoxically, Heinlein also then wrote *Stranger in a Strange Land* (1961), from which American hippie readers enthusiastically co-opted the term *grok* for intimate understanding (as in free lovemaking), although they misconstrued Heinlein’s underlying libertarian attitude. In retrospect, some see Heinlein as typifying male chauvinist science fiction. Paradoxically as well, his first novel in manuscript, *For Us, The Living*, written in 1939, describes a man who clashes with, and eventually accepts as wholly justified, a 2086 future in which women have social and career equality with men (this rejected manuscript was not published until 2004, after Heinlein’s death).

In the late 1960s, science fiction began to draw more female authors and readers. A readership consisting of budding engineers and scientists gave place to social science and humanities students, while technological innovation, space war, and abstract ideas gave way to psychological and stylistic experimentation. The quietly egalitarian 1950s work of such science fiction writers as Judith Merril (1923–1997) and Katherine Maclean gave way to Joanna Russ’s brilliantly feminist *Female Man* (1975), Ursula LeGuin’s novels, and Alice B. Sheldon’s (1915–1987) many short stories (published under the pen name James Tiptree Jr.). There were also “crossover” figures such as Kurt Vonnegut (1922–2007), who began his career in science fiction and then smoothly switched to a broader “mainstream” readership. Doris Lessing established her reputation as a mainstream writer but has also written much that is science fiction in content terms. In 1976 Octavia Butler (1947–2006) published *Kindred*, whose contemporary African American protagonist time travels to the antebellum South. Butler’s Exogenesis series explores issues of sexual identity, sexuality, and power, blurring lines between science fiction and other literatures. Butler’s work won her a coveted MacArthur Fellowship in 1995. In the 1980s and 1990s, Orson Scott Card dazzled the science fiction community with *Ender’s Game* (1985), *Speaker for the Dead* (1986), and *Xenocide* (1991), infusing traditional science fiction with computer gaming and winning a large youth audience. A practicing Mormon who has complained that science fiction did not take religion seriously, Card has also written explicitly scriptural stories.

The term *mainstream* was adapted by the middle of the twentieth century to distinguish “literature” from specialized, not-quite-literary genres such as science fiction, horror stories, romance fiction, spy stories, and crime fiction (bookstores often arrange their shelves in accord with this distinction). At the same time, however, this breakdown can seem increasingly dubious. For one thing, older books tend to migrate to the literature shelves. Mary Shelley’s *Frankenstein*, H. G. Wells’s *The Time Machine* (1895), and Verne’s *From the Earth to the Moon* will be found there, along with Fyodor Dostoyevsky’s *Crime and Punishment* (1855) and Edgar Allan Poe’s (1809–1849) horror stories. Graham Greene (1904–1991), who made his mark as a crime and espionage writer, is now wholly included in the literature sections of libraries and bookstores. “Classics” sections may include not only Poe, Wells, Greene, and Dostoyevsky, but also Arthur Conan
Doyle's (1859–1930) Sherlock Holmes detective stories and LeGuin's and Lessing's writings, alongside such long-celebrated “literary giants” as Ernest Hemingway (1899–1961) and William Faulkner (1897–1962). Moreover, the centrality and celebrity once granted literary figures now generally envelops only writers, stars, and producers of movies and television. Quite simply, story writers such as Mark Twain (1835–1910) and O. Henry (1862–1910) were the most famous, most widely enjoyed, and best-paid professional entertainers of their day. Even as late as 1952, the issue of Life magazine that carried Hemingway's The Old Man and the Sea sold over five million copies in two days. Arguably, Hollywood and television comprise the only “mainstream” today.

SEE Management.

**SCIENTIFIC METHOD**

Research is scientific if and only if it follows a procedure known as scientific method. A received view of this method has evolved in the seventeenth century as a synthesis of ideas of Bacon, Boyle, and Newton. Roughly, scientific method consists of indiscriminate observations of regularities, gathering information on repeatable phenomena, and using it as a sound basis for theorizing. Scientific method is, then, a talisman for success. Accordingly, researchers strive to show that their work conforms to scientific method—to the point of distortion. Yet, famously, all guarantees of success in research are worthless. Plato declared that the validity of ideas depends on their pedigree. Tradition offers only two views on the source of ideas: It is intuition—intellectualism, apriorism (Plato)—or it is observation—empiricism, inductivism (Aristotle).

Question: Where should thinking or observing begin? No answer. Reliance on both thought and experience as sources of knowledge is impossible, as they may mismatch; yet their judicious use as procedures is possible: Apriorism admits experience as hints; inductivism admits hypotheses as temporary scaffolding.

The promise of success that scientific method grants depends on the unlearning of prejudices. Sir Francis Bacon, the father of the modern scientific method and a precursor of the Enlightenment, was the first to realize that preconceived opinions distort observation, as they invariably confirm themselves; reliable observations come from unbiased minds. So he recommended relinquishing all preconceptions. This is radicalism; it bespeaks utter rationality. The classical rationalists of the Age of Reason viewed humans as utterly rational, with reason as free of local (individual) differences. Their theories ignored these differences; their economic theory concerned only free trade; their political theory deemed the state as taking care of the contracts, including those between ruler and subject; religion they viewed as private, independent of any established church. Social researchers thus viewed individual conduct as purely rational and as yielding to individually endorsed motives exclusively. Thus, their views on scientific method embody a view of humanity as rational and the individual as preceding society.

The received view of scientific method remained excessively rationalist, radical, historical, individualist, and liberal. To date it dominates the natural sciences, economics, and behaviorist and Freudian psychology. After the failure of the French Revolution, the dominant view within social studies had history as its paradigm, and its agenda largely aimed at shunning radicalism by presenting political theory historically, deprecating democracy and science. As views on scientific method differed, so views differed as to whether social studies start with individuals and reach the study of the social whole or vice versa. This was then a backlash against radicalism. Its prime initiator was Georg Friedrich Wilhelm Hegel, who traced the roots of French revolutionary terror to the Enlightenment's dismissal of social authority as resting on prejudice. Scientific method is inapplicable to society, he declared, since societies have historical roots; there is no social prediction even though nations are subject to historical laws. Schelling, Hegel, and others, developed new methods, variants of which some twentieth-century thinkers embraced, especially Henri Bergson and Edmund Husserl. Following Hegel's claim that the methods of the natural and social sciences diverge, Wilhelm Dilthey suggested that whereas the natural sciences employ deductive explanations, the social sciences employ empathy. (Karl Popper endorsed this distinction, incidentally: His theory of explanation—situational logic—encompasses both
models, and allows for reference to both individuals and institutions.) Hegel's methodology is still popular among those who ignore scientific method. Conspicuous among his twentieth-century followers are Gabriel Marcel, Paul Ricoeur, Martin Heidegger, Hans-Georg Gadamer, Jean-Paul Sartre, and Jacque Derrida. They all adopted variants of Husserl's method. Heidegger preferred poetic truth to scientific truth. Gadamer endorsed Hegel's objection to the Enlightenment movement's sweeping dismissal of prejudice. He recommended the study of texts, not of facts, hoping that certitude is achievable there, with wider conclusions. Derrida objected: There is no one certain way to read a text. Gadamer was adamanat, expressing preference for Aristotle's text on physics over modern ones. Sartre first accepted scientific method and endorsed behaviorism. As he was later impressed with psychoanalysis, he gave up both. (Incidentally, Popper considered both violations of the rules of scientific method, as he rejected the received view.)

Hegel also influenced adherents to science, including Henri de St. Simon, Auguste Comte, John Stuart Mill, and Karl Marx. They sought the scientific historical laws that permit predictions. Marx stressed that scientific method sanctify his predictions, rendering them uncontestable. (Not all his followers share his respect for science.) Does the use of scientific method validate Comte's theory of the three stages of history or Marx's view of history as propelled by the class struggle? Is dissent a challenge to their scientific credentials? Or did prejudice distort their use of scientific method? These are difficult questions.

William Whewell, a significant nineteenth-century transitional figure, dismissed the fear of prejudice. He contested Bacon's proposal to empty our minds of preconceived opinions, declaring all ideas preconceived. He trusted rigorous tests to eliminate error. Bacon promised that empty minds will follow scientific method and produce true theories; Whewell denied that: We need hypotheses; occasionally, researchers hit upon true ones and verify them empirically, he said. His view won popularity among physicists while social thinkers followed Mill.

Marx challenged the individualist, ahistorical economics with his historical prediction: As markets must be increasingly unstable, capitalism will give way to socialism—probably through civil war. At the end of the nineteenth century, Émile Durkheim and Max Weber, known as the fathers of modern sociology, circumvented him and shifted the debate away from history back to the other question that Hegel had raised: Which is primary, the individual or the social whole? Their writings on society and on scientific method ignore historical laws.

Durkheim's starting point was the claim that some "social facts" are observable (such as conformity to laws). This is hard to comprehend, but clearly, he wanted to broaden classical individualist methodology to make it recognize collective entities. He steered between Hegel's view of social forces and Marx's view of economic forces. He considered national cultures to be the glue that maintains collectives; in particular, religion is society's representation or celebration of itself.

Durkheim valued individual contributions to culture, as he admired science. Does his view of culture allow for this? He left this question open. Hence, as a response to Hegel, his theory is incomplete. His attention lay elsewhere: He insisted that a culture coheres with its society. He invented functionalism, the view that social wholes are coherent. A clear counterexample to this is crime: It is dysfunctional. He suggested that crime has a function: to remind society of the law. This does not block the counterexample: The need for violent reminders bespeaks incoherence. Once functionalism incorporates dysfunctional aspects, it becomes trivial and abandons coherence. Durkheim was inspired by Claude Bernard's observation that cold-blooded animals are more adapted to the environment but less energetic than warm-blooded ones. He applied this to the division of labor: High specialization enables a striking worker to bring society to a halt and forces it to cohere (organic solidarity). This is too vague to be open to criticism.

Weber rejected "one-sided materialism"—in allusion to Marx—and ascribed social values to ideas. His studies identify typical value-systems of typical members of various classes and societies. Unlike classical individuals who represent humanity in general, Weber's typical individuals represent subcollectives. His theory of scientific method thus steers between classical individualism and collectivism. To emphasize his reluctance to say whether societies are real, he called it "individualism of method."

Georg Simmel (a contemporary of Durkheim and Weber, but influential only after World War II) suggested that individual and society are equally primary, so that conflict is never totally avoidable. Karl Popper suggested considered action as strictly individual but within social contexts—situational logic—thus achieving a view that is in the traditional individualist mode, without being radical. This opens the road for new kinds of explanation—especially for actions aiming at institutional reform.

Popper's suggestion rests on his groundbreaking description of scientific theory as (not proven but) testable, namely, refutable. For success, this is necessary but insufficient: There is no guarantee. Scientific truth is then not the truth, but the best available approximation to it. This closes the debate comparing the rules for natural and social studies. For explanations in the social sciences to be refutable, they should center on individual actions.
Science is now increasingly seen as the search for answers to interesting questions that are open to criticism.

Another development is of the systemist outlook: Both individual and society are systems of sorts (Mario Bunge). How is action at all possible? This question is outside the domain of social studies; these take actions as given and center on their unintended consequences (Hayek)—especially actions intended to improve society. Systemism is incomplete without a theory of scientific method. Some variant of Popper's theory is an obvious candidate. This, however, is a matter for future discussions of scientific method adequate for social studies. The starting point of any such study has to be an examination of the history and sociology of the social sciences, especially of the question, what do we owe to the diverse school of thought of the past and to their august members?

BIBLIOGRAPHY

Joseph Agassi
While scientism has its roots in the work of Francis Bacon, Auguste Comte, Herbert Spencer, and other pre-twentieth-century writers, the term itself was first used by French writers in the 1930s. It was introduced into English by the economist Friedrich A. von Hayek (1899–1992) in several publications in the 1940s that were later collected in his book *The Counter-Revolution of Science* (1952). Hayek presented several arguments that later became central to critiques of scientism:

1. that meaning and intention are essential to understanding human action and social phenomena generally and that these are not reducible to physical terms;
2. that the social sciences seek to understand unique, particular phenomena as well as those that can be subsumed under general laws and that context is essential to explaining such phenomena; and
3. that much of the quantification prevalent in the social sciences is inappropriate, copying the form rather than the substance of physical science.

These arguments are prominent in what later became known as the “interpretive” approach to social science. The German theorist Jürgen Habermas (b. 1929) raised additional arguments against scientism, challenging the traditional separation of science and politics as well as asserting the social sciences’ need for interpretive and situation-specific understanding.

While the reductionist version of scientism has sometimes been promoted by physical scientists and philosophers, twentieth-century debate in the social sciences largely focused on methodological issues and the ontological assumptions that inform them. The main arguments against scientism have been grounded in social constructivism, the view that we construct, rather than simply discover, the nature of the world. This view entails that scientific knowledge is simply one construction among others and has no exclusive claim to preeminence or truth. These arguments have informed both the methodological debates in the social sciences, often called the “paradigm wars,” between quantitative and qualitative approaches and the broader critique of science itself (the “science wars”), most prominently in what has been called the “critical sociology of science.” The latter combines social constructivism with Habermas’s political analysis of science to argue that the authority of scientific “knowledge” derives not from any legitimate claim to “truth” about the world but from the rhetorical and political strategies used by scientists to promote their claims.

The “paradigm wars” were widely seen as waning during the last decade of the twentieth century, accompanied by increased acceptance of qualitative and interpretive research and the rise of what has been called “mixed methods” research, combining qualitative and quantitative approaches. In the early twenty-first century, however, scientistic views have gained renewed prominence and political support, particularly in British and American educational policies, where experimental methods have been promoted as “science-based” research, in opposition to the diversity of methods traditionally used in educational research. Attempts have been made to develop a middle-ground position, although some of these have been criticized as still incorporating scientistic assumptions.

Philosophers have also attempted to develop a middle ground between scientism and radical constructivism. One such attempt is the development of critical realism as an alternative to both empiricism and constructivism. Critical realism combines a constructivist epistemology (our understanding of the world is to a significant extent socially constructed) with a realist ontology (the world exists independently of our constructions and influences the success of those constructions). Similar views are widespread in the philosophy of science. A parallel critique has challenged the narrowly logical definition of science and scientific method promoted by positivist philosophers and emphasizes the grounding of scientific methods and understanding in our commonsense activities as inquirers. In combination these arguments support both the methodological and the antireductionist critiques of scientism and promote a broader understanding of science that is compatible with methodological and conceptual diversity. They do so while avoiding the relativism of radical constructivism and affirming the value for the social sciences of scientific concepts, such as causal explanation.

**SCOPES, JOHN**

**SEE** Scopes Trial.
SCOPES TRIAL

The dramatic Scopes “Monkey Trial” in 1925 involved the prosecution of high school science teacher John T. Scopes (1900–1970) for violating Tennessee’s Butler Law, outlawing the teaching of evolution in the state’s public schools. The trial was one of American history’s landmark courtroom battles and a watershed in what came to be widely understood as a cresting conflict between science and religion.

The publication of Charles Darwin’s *Origin of Species* in 1859 was taken by many as a radical challenge to the Biblical accounts of humankind’s origin. In the ensuing years, revolutionary advances in science and technology, increasing urbanization, and the growth of religious pluralism fed by mass immigration, buoyed both the self-confidence of science and the appeal of a secular public sphere. Evolutionary theory was applied to social relations to justify the laissez-faire (or hands-off) policies and economic inequalities of the Gilded Age (which many Christians condemned) as naturally occurring instances of the survival of the fittest. Prominent public thinkers increasingly argued that religion was dogmatic, superstitious, and impeded the scientific spirit essential to a more enlightened modernity. The 1920s, however, witnessed a revival of Fundamentalist Protestantism, aimed at fighting these trends, and many of the ideas—like evolution—that undergirded them by undermining the authority of Scripture. Part of the Fundamentalist counterattack involved state-level efforts to outlaw the teaching of Darwinian theory to public school children.

The Scopes trial was self-consciously conceived as a theatrical staging of these broad-ranging social debates. Tennessee’s Butler Law was passed largely as a statement of principle. Few of its proponents either intended or expected that it would be aggressively enforced. The proponents of evolutionary theory, scientific investigation, academic freedom, and secular education (including the American Civil Liberties Union) actively recruited John Scopes, a general science teacher substituting as a biology teacher, to admit to having violated the law by teaching a lesson in evolution. They did so in full collusion with local town officials in Dayton, Tennessee (including the prosecutor), who hoped a dramatic public spectacle pitting the claims of science against religion would revive the economic fortunes of the ailing southern town. The town officials bore no ill will toward Scopes, who swam with the opposing side’s lawyers during trial recesses. It was understood that, if convicted, Scopes would serve no jail time, but instead pay a fine generously provided by others. The prosecution and defense teams recruited two of the country’s most famous lawyers to square off on behalf of science on one hand and the Bible on the other—the radical Chicago attorney (and proud atheist) Clarence Darrow (1857–1938) and the Populist evangelical former presidential candidate and secretary of state William Jennings Bryan (1860–1925), respectively. The trial was conducted in a carnival-like swirl of hot-dog and lemonade hawkers, souvenir vendors, and street-corner orators. The proceedings were broadcast live from Chicago on WGN radio and charted by swarms of reporters, including the celebrated American journalist H. L. Mencken (1880–1956). The sparring between the two lawyers, including Darrow’s withering cross-examination of Bryan (who mounted the stand himself as an expert on biblical teaching) became the stuff of legend. Although the jury convicted Scopes, the consensus was that Darrow had effectively humiliated the creationists, striking a powerful blow for science and academic freedom. Many have held the trial’s grueling ordeal responsible for Bryan’s death only days after the verdict, as well as for the ensuing retreat of many fundamentalist Protestants from the nation’s public life.

In subsequent years the Scopes trial retained a rich resonance as a symbol of the dangers of not only religious zealotry, but of religion in general, to the advancement of knowledge and intellectual freedom. These symbolic uses were evident in accounts of it in the most prominent cold war era American history textbooks and, most famously, in the Jerome Lawrence and Robert E. Lee play, *Inherit the Wind* (and its 1960 film adaptation by Stanley Kramer), which took dramatic liberties with real events by building up the depth of John Scopes’s commitment to evolutionary theory and academic freedom and the ruthlessness and intolerance of the Dayton townspeople and prosecutors. These reconstructed memories were prominent in the culture at precisely the moment in the early 1960s that the U.S. Supreme Court held—in a run of Establishment Clause cases invalidating Bible reading and prayer in the schools—that the Constitution imposed a “high and impregnable” “wall of separation” between church and state. As evangelical and fundamentalist Christians became newly active in politics in the 1980s (in part in reaction to these judicial rulings) and as a new generation of critics of evolutionary theory and proponents of creationism and “intelligent design” gained influence, the meaning and legacy of the Scopes Trial are being reconsidered once again.

SCOTTISH MORALISTS

The term moralist as used here is historically and technically specific. It describes loosely related but mutually supporting intellectual positions in modern metaphysics and epistemology; in morality, civil society, and the law; in economic and political theories; and in cultural history. Therefore the group of Scottish thinkers who are individually and collectively called moralists, though without unanimity in the details of their beliefs, share, in a general and in identifiable ways, compatible views on the nature of philosophy, social science, and politics.

These thinkers are easily identifiable in part because their mature professional lives were spent largely in Scotland, particularly—though not exclusively—at the universities of Glasgow and Edinburgh. Furthermore, their ideas blossomed and their influence radiated from Scotland out to the major centers of learning in modern Europe and beyond roughly between 1740 and 1800. It was in these sixty years that the most influential works were published by the Common Sense philosopher Thomas Reid (1710–1796), the Skeptical philosopher and historian David Hume (1711–1776), the economist Adam Smith (1723–1790), the jurist and cultural historian John Millar (1735–1801), and the sociologist and political scientist Adam Ferguson (1723–1816). Others whose works were part of the moralist trend before, during, and after the sixty-year period and who are privileged for the sake of analysis include: Francis Hutcheson (1694–1746), the jurist Henry Home, Lord Kames (1697–1782), the philosopher and biographer of Adam Smith, Dugald Stewart (1753–1828), and the economist James Mill (1773–1836). Also worthy of mention are James Ramsey McCulloch, Thomas Chalmers, Thomas Carlyle, William Robertson, James Boswell, James Hutton, Robert Wallace, and James Watts. Though born in Ireland to Scottish parents, the Utilitarian philosopher Francis Hutcheson is usually associated with the Scottish moralists because of his influence on Hume and Reid. Hutcheson’s impact at the University of Glasgow, where he taught for many years, was so profound that some regard him as a founding father of the Scottish Enlightenment.

SCIENTIFIC AND CULTURAL CONTRIBUTIONS

In its technical details, it is obvious that Scottish moral philosophy could not have been possible without Copernicus, Bacon, Galileo, Kepler, Boyle, and Newton. The works of these men transformed not just what scientists studied but also, more importantly, the method of inquiry itself. The development of fact-based methods of scientific research—as opposed to idealistic speculative rationalism—directly paved the way for a new kind of philosophy: empiricism. As scholastic speculation and discourse became supplanted by physical observation, measurement, and mechanical experimentation, philosophers like Hume responded by developing a skeptical approach toward traditional metaphysical problems. Hume’s self-described “new” philosophy aimed to be grounded in, and reconciled with, the Newtonian and other mechanical and materialistic disciplines. For Hume, skepticism about the existence of the soul, causality, and the possibility of miracles were some of the natural results of his effort—to quote the subtitle of his Treatise of Human Nature—to “introduce the experimental method of reasoning into moral subjects.”

WHY SCOTLAND, WHY THEN?

SOME HISTORICAL BACKGROUND

When the kingdoms of England and Scotland were united under King James VI in 1707, Scotland was in the midst of a series of so-called Jacobite revolutions: The first occurred in 1690, the second in 1715, and the last in 1745. These social and political upheavals left Scots not just with a sense of cultural and national instability but also faced with economic challenges that would prove transformative. In order to keep up with its English and French neighbors, Scotland was forced to modernize its economy.

But competition with England and France transcended the domains of the purely political or economic. Cultural issues were never far behind. For example, in England and France it had become a matter of national pride among philosophers, scientists, and playwrights to publish or produce in the national vernacular. It was therefore notable when, in 1729 at the University of Glasgow, Hutcheson became the first to give a lecture in English rather than Latin.

A transformed political culture, the search for economic prosperity through modernization in the context of international competition, and the emergence of a dynamic civil society—these are some of the key factors that account for the national, cultural, and class coherence that characterizes a significant number of the group of thinkers and theorists we call the Scottish moralists.
One of the consequences of empiricist epistemology was antifoundationalism, not just in regard to interpretations of religious beliefs (like the belief in miracles), but also in the conceptions of popular morality and social ethics. Utilitarianism, inspired both by the empirical sciences and the new political sciences of writers like Hobbes, became a widely accepted perspective. Hutcheson was the first to use this term to mean “the greatest happiness for the greatest number,” though he did so in response to Hobbes and Hume. Hobbes claimed that individuals acted, however indirectly, only out of self-interest and never altruistically. Hume’s own methodological and substantive skepticism led him to draw the conclusion that the foundations of both individual and social morality were merely customary and conventional: Neither religion nor metaphysics can guarantee that our ideas of the proper and improper, right and wrong, good and bad, or beautiful and ugly are transcendentally grounded.

Empiricism and utilitarianism combined to produce the doctrine that individuals merely act out of self-interest and to seek pleasure and avoid pain. The doctrine in turn made it possible to say that neither religion nor morality nor aesthetics required, for their explanations, theological or metaphysical foundations. Hutcheson, for example, argued that individuals naturally value society and therefore naturally work cooperatively to achieve it, simply because of their naturally based capacity for feeling or sympathy. It is sympathy that leads otherwise unrelated and self-interested individuals to think and act benevolently toward one another. The task of culture and civilization was merely to promote this fellow-feeling, so that in society persons not only compete but also cooperate for the common good. It is ultimately fellow-feeling and a sense of mutual belonging that leads to well-ordered civil society, national peace, and commercial prosperity. One of the obvious consequences of Hutcheson’s social and political philosophy is that being virtuous (e.g., doing what is proper, right, or good), because untethered from earlier theological and metaphysical moorings, amounts to a commitment in personal thought and action to increasing the “degrees of happiness” both for oneself and for all.

Empiricist and utilitarian theories also took hold in the sphere of economic thought. Adam Smith not only accepted the idea that individuals acted out of self-interest but also promoted this self-interest both as a particular kind of natural psychology and as a form of social rationality. In The Wealth of Nations (1776), a book considered the founding text of modern economics, Smith translated the original insights of utilitarian ethics into the argument that what is economically selfishly good for the individual is also generally good for the welfare of society. Smith notes: “As every individual ... endeavours as much as he can both to employ his capital in the support of domestic industry, and so to direct that industry that its produce may be of the greatest value; every individual necessarily labours to render the annual value of society as great as he can” (IV, 2.9).

In his famous phrase, the “invisible hand,” Smith captured what he thought was going on in any prosperous economy. Dynamic and free commercial relations occur, in nearly mysterious ways, as a result of equilibrium between supply and demand. This equilibrium occurs not because individuals are acting selflessly, nor is it a result of heavy-handed government regulation or of business cartels and monopoly. Rather, market equilibrium is simply an empirical fact based on the psychology of the individual. The self-interested actor “neither intends to promote the public interest, nor knows how much he is promoting it” (IV,2.9). Thus it is the mere effort to look out for one’s own economic interests (“he intends only his own security ... he intends only his own gain”) that makes the actor automatically “led by an invisible hand to promote an end which was no part of his intention” (IV.2.9). In even more colorful language, Smith anticipates objections to his observations by pointing out that it is “not from the benevolence of the butcher, the brewer, or the baker that we expect our dinner, but from their regard to their own interest” (IV.7.26).

Moreover, Smith believed that a society is worse off in a government-regulated economy. Market forces alone appear to successfully ensure that an individual, “by pursuing his own interest ... frequently promotes that of society more effectually than when he really intends to promote it” (IV.2.9). Smith was, accordingly, entirely skeptical about any hope that “much good [can be] done by those who affected to trade for the public good” (IV.2.9). This position provides the reasoning behind the laissez-faire doctrine in classical economics, a doctrine whose origin is rightly attributed to Smith.

What stands out the most in the above-mentioned moral, social, and economic theories is confidence in the autonomy both of the individual and of society. This confidence translates into the belief that a society and its culture—its history—can be consciously made and remade. It inspired the moralist intellectuals to propose progressive theories of history. In their writings, the word development acquired an explicitly historical character. Against the feudal worldviews shaped predominantly by traditional attachments to class and land, in which social hierarchies were justified by religion and theology, the moralists proposed a conception of history as a domain controlled by autonomous individuals and their collective quest for rational self-determination. In addition to Smith’s Wealth of Nations, Lord Kames’s Essays on Principles of Morality and Natural Religion (1751), John Millar’s Observations Concerning the Distinction of Ranks in Society (1771),
Ferguson’s *An Essay on the History of Civil Society* (1767), and William Robertson’s *The History of Scotland* (1794) were each in the forefront of developing the argument that rather than being fated by God or Nature to follow an inexorable path, any society, if based on the psychology of the individual, could be socially progressive and economically prosperous. The scientific study of society and history—in short, the rise as independent and empirical fields of research of such social sciences as psychology, economics, anthropology, sociology, legal history, and cultural theory—had its modern beginnings in many of the insights generated or expanded upon in the works of the Scottish moralists.

The moralists’ theory of history helps explain why it is not surprising to discover in some of their writings prejudice against cultures and societies perceived as “backward,” static, and nonprogressive. Their evolutionary view of society led them to try to determine the direction of universal progress and to position existing societies and cultures in hierarchical classificatory schemes, using what they supposed were empirical scales of measurement. Smith, for example, believed that societies and ultimately global history progressed through several stages, defined by economic and political activities: The series of stages begins with hunter-gatherers, then progresses through stages characterized by nomadic tribes, sedentary farmers, feudal states, and mercantile societies, before culminating in industrial urbanization. The secret to industrialization, according to Smith, was division of labor, a method capable of producing the largest quantity of goods for the largest number of people by the most market-efficient methods.

Because of their evolutionary conception of societies, Scottish moralists were not disturbed by imperial expansion and colonial conquest. Imperialism and colonial conquest, in Ferguson’s view, for example, promoted commercial activities and transformed culturally and economically “primitive” nations into industrial or industrializing countries or trading partners. Indeed, because of its wide influence the work of the Scottish moralists cannot be decoupled from the contradictions that attended the development of modernity throughout Europe, Africa, and the Americas: Even as the capitals and provinces of Europe and the Americas were championing the idea of historical progress and the “rights of man,” a great deal of the growth in the world’s local and international economies was based on slave trade and slave labor, imperialism, and colonialism.

**INFLUENCE AND LEGACY**

The influence of the moralists on the transformation of Scottish society can easily be measured. On January 8, 1696, for example, a young man by the name of Thomas Aikenhead was executed for blasphemy. A university student, Aikenhead was successfully charged with “denigrating” the Bible. But public records of the proceeding suggest that Aikenhead was viewed to have committed something more offensive. Though he said he believed in the Holy Trinity, he also, by his own confession, believed that moral laws were “the work of governments and men” and had said to fellow students that theological arguments produced to show otherwise were “a rapsodie of feigned and ill-invented nonsense” (Hill N.D.). By 1755, however, Scotland itself had changed. This was the year David Hume was formally charged with an offense anyone might have considered far more grievous, namely, atheism. Moreover, like Aikenhead, Hume had published books arguing that morality was justified entirely by tradition and custom. Yet, the charges brought against him were dropped—for lack of cause.

Beyond Scotland, the moralists were at the cutting edge of the wider social and political movement known as the Enlightenment. In the decades 1740 to 1800 the Enlightenment movement both became a more universal phenomenon and took on local coloration not just in the cities of Glasgow, Edinburgh, Paris, London, Berlin, and Philadelphia, but also in lesser-known centers of commerce and learning such as Bristol, Cartagena, La Fleche, Konigsberg, and Axum. In the same sixty-year period, three of the modern world’s most significant political transformations occurred: the American, the French, and the Haitian revolutions. The direct connections between these revolutionary developments included the international evangelical and moral revivals represented by activist groups like the Society of Friends, popularly known as the Quakers. In London, influential Quakers formed The Meeting on Slave Trade and worked with Thomas Clarkson and William Wilberforce in the cause of abolition of the slave trade. In the Americas, particularly Philadelphia, Quaker leaders of opinion like John Woolman and Anthony Benezet worked with atheists and believers alike—Thomas Paine, Benjamin Franklin, Joseph Priestley, among others—to found in 1775 and promote what became the first abolition society anywhere in the western world: the Pennsylvania Abolition Society. In Paris, revolutionary clergymen like Abbé Grégoire formed complementary international abolitionist associations, including *La Societé des amis des noirs*, an organization which became influential as a source of moral and material support for the revolutionary black slave and ex-slave populations of the French colony of San Domingue, today’s Haiti. These international networks grew out of strong and deep grassroots moral awakening. For example, at its 1754 governing meeting in Germantown, Pennsylvania, Quaker representatives drafted and adopted a formal declaration that, in the language of the Enlightenment social movement, its members “shall never
think of bereaving our fellow creatures of that valuable blessing, liberty, nor endure to grow rich by their bondage.” The document goes on to admonish the rest of the world that “to live in ease and plenty by the toil of those whom violence and cruelty have put in our power is neither consistent with Christianity nor common justice” (The Philadelphia Yearly Meeting of the Society of Friends 1754). The influential roles of the Quakers in the abolitionist movement and in the birth of modern world wide human rights campaigns have been chronicled by Adam Hochschild in Bury the Chains: Prophets and Rebels in the Fight to Free an Empire’s Slaves (2006) and King Leopold’s Ghost: A Story of Greed, Terror, and Heroism in Colonial Africa (2006).

In technical philosophic and scientific matters, the legacy of the Scottish moralists can be seen throughout the world in the subsequent development of philosophy and in the growth of the social sciences. The antifoundationalist tenor of their works provoked other thinkers to raise questions that had remained hidden. Immanuel Kant, for example, credits Hume’s skepticism for helping to awaken in him the questions he formulated and tried to answer in the Critique of Pure Reason (1781). The field of modern economics can hardly be said to exist prior to Adam Smith, and Thomas Reid’s Common Sense conception of truth and objectivity is echoed in the works of the twentieth-century American psychologist William James and the sociologist George Mead. In fact, in contemporary psychology and medicine, there is a distinct subfield called symbolic interactionism, in which it is argued that it is only in society that the most valued human qualities—e.g., our conceptions of the self and of the individual—are generated. In twenty-first-century philosophy, under the name extended mind or external mind, one finds equivalent social-environmentalism in the conceptions of consciousness and moral agency. Some of these newer research projects in this area draw on the strengths of moralist psychology and social theory while at the same time challenging their ethnocentric aspects.

Some aspects of twentieth-century existentialism also reflect prior developments in “moralist” conceptions of freedom and of history. For example, environmentalism notwithstanding, moralist ego psychology makes it possible to believe that though nature and society may predispose an individual to certain actions, it is only weakness of will or, in the case of illness, natural impairment that robs the individual of control over their decisions, or over the actions based on those decisions.

Finally, social theory from Nietzsche to Marx—specifically, moral psychology and political economy—benefited from the insights of the Scottish moralists. For both Nietzsche and Marx, hypocrisy and lack of transparency in moral and economic relations are “mystifica-

SCREENING AND SIGNALING GAMES
An agent with private information who takes a costly action in order to favorably affect the responses of others is “signaling.” A responding agent who precommits to a response that is contingent on the informed agent’s action is “screening.”

In Michael Spence’s seminal paper (1973), a worker signals her value by her choice of education. Firms base their beliefs about a workers’ productivity based on her educational choice and compete for her services. In the simplest case there are two types of worker, with values $v_1$ and $v_2 > v_1$. The cost of achieving an educational credential $z$ for a type $t$ worker is $c_t(z)$. Spence asked under what conditions it would pay the high value worker to signal by choosing to add to her educational credentials, even in the extreme case in which the education had no direct effect on productivity. Suppose that there is such an education level $z_1$ selected only by a high-value worker. That is, the equilibrium outcome separates the different types. Given that there is separating, competition by firms results in a wage offer of $v_1$ for those without the educational credential and a wage offer of $v_2$ to those with the credential. For this to be an equilibrium, each type of worker must have an incentive to take the anticipated action. Hence the following incentive constraints must be satisfied:

\[
IC_1^*: v_1 \geq v_2 - c_1(z) \\
IC_2^*: v_2 - c_2(z) \geq v_1.
\]

Let $z$ be the education level where the first constraint is satisfied with equality and let $\bar{z}$ be the education level where the second constraint is satisfied with equality. As long as the high-value worker has a lower cost of education, $z < \bar{z}$ and any education level $z_1 \in [z, \bar{z}]$ satisfies the two incentive constraints. Note that a smaller $z_1$ is less costly for the high type. Thus, for Pareto efficient separating, the incentive constraint for the low type is binding.

APPLICATIONS
From this basic idea a vast applied literature has emerged. In the insurance industry it has been argued that deductibles are used to separate risk classes, because a good risk has a smaller probability of incurring the deductible and hence a smaller cost of signaling. For new products, advertising has been explained as a signal, because if the quality is low, the firm will incur a loss of revenue due to reduced future sales, as consumers experience the good. Similarly, a high introductory price can signal high quality, as long as there are a sufficient number of fully informed consumers.

In the theory of bargaining between a firm and union, the delay between an offer and a counter-offer is a potential signal. Suppose that bargaining with full information leads to agreement over how the pie should be shared. The firm only knows whether revenue will be high or low. The opportunity cost of delay is lower for a low profit firm, so the union is willing to accept that the pie must be smaller and thus accept a lower wage.

Signaling theory has also been used extensively in finance to show how the underpricing of an initial public offering (IPO), the capital structure, and the issue of double-taxed dividends can all be used to signal a firm’s profitability.

In macroeconomic policy analysis it has been argued that a government can credibly signal its commitment to “tough” future economic policy by taking a tough action in the current period. The net cost to taking this action is lower for a government that really does value the future benefits of (for example) a sustained anti-inflationary policy. Similarly, a government can signal its long-term com-
mitment to trade liberalization by taking a tough action in the current period.

DEVELOPMENT OF THE THEORY
Spence's original work followed largely in the Walrasian tradition. Michael Rothschild and Joseph Stiglitz (1976) argued for a formal game-theoretic foundation. In their analysis, the uninformed agents move first, making commitments as to how they will respond. That is, the firms make screening offers. They showed that in such a model there may be no Nash equilibrium, and concluded that competitive markets can perform poorly.

More recent theory has focused on signaling games in which the informed agent moves first. Suppose, in the Spence model, that the informed agent believes he will be paid a high wage if and only if he chooses an education of at least $z_2 \in [\bar{z}, \underline{z}]$. Given such beliefs, the two types separate. Because any education level on this interval will suffice, there is now a continuum of Nash separating equilibria. But what beliefs are plausible if the informed agent chooses a smaller education $\bar{z}$. This question is at the heart of a large theoretical literature on refinements of Nash equilibria (Intuitive Criterion, Divinity, Stability). The most popular of these refinements is the Intuitive Criterion of In-Koo Cho and David Kreps (1987). Their basic idea is that an informed agent will take an out-of-equilibrium action when (1) she will be better off if the responders correctly infer her type, and (2) given this belief, all other types prefer their Nash equilibrium action. The efficient separating equilibrium is the unique Nash equilibrium that satisfies this restriction on beliefs. This question is at the heart of a large theoretical literature on refinements of Nash equilibria (Intuitive Criterion, Divinity, Stability). The most popular of these refinements is the Intuitive Criterion of In-Koo Cho and David Kreps (1987). Their basic idea is that an informed agent will take an out-of-equilibrium action when (1) she will be better off if the responders correctly infer her type, and (2) given this belief, all other types prefer their Nash equilibrium action. The efficient separating equilibrium is the unique Nash equilibrium that satisfies this restriction on beliefs. This is readily illustrated. Consider the education levels $z_2$ and $\bar{z} < z_2$ on the interval $[\bar{z}, \underline{z}]$. By construction, a low-value worker is better off earning his true value $z_1$ than paying for an education at these levels. Thus, by the Intuitive Criterion, a worker choosing $\bar{z}$ will be perceived to be high value. Given such beliefs, high value workers have an incentive to choose the less costly education $\bar{z}$. Arguing in this way, only the Pareto efficient separating Nash equilibrium can satisfy the restrictions on beliefs imposed by the Intuitive Criterion.

SCRIPT MODELS

A script is a type of schema, or implicit mental representation, that describes an expected sequence of events. Scripts are developed from experiences with particular situations, from which information is abstracted and organized so as to guide thinking, feeling, and behavior when encountering similar experiences in the future. In a collaboration between the fields of artificial intelligence and social psychology, Roger Schank and Robert Abelson (1977) introduced a script model to explain people’s understanding of socially stereotypic events such as eating at a restaurant. From the fields of social, personality, and clinical psychology, a script model has been employed to understand people’s experience of emotionally significant and personally idiosyncratic events such as negotiating relationship conflict (Baldwin 1992). For example, a script might specify that in the context of conflict with an intimate other, if the other expresses anger, the self will feel regret and act submissively to achieve resolution of the conflict.

Models of scripts for socially stereotypic events emphasize that scripts enable people to automatically comprehend a variety of experiences through a cognitive structure that provides both power and economy. Models of scripts for personally significant events emphasize that scripts serve an individual’s motivation to anticipate and deal with emotional experiences to maximize positive emotion and minimize negative emotion. In either case, script models depict people as creating scripts by extracting the important elements of scenes they have experienced and connecting similar scenes together. Evidence suggests that children less than one year old begin to make such connections between scenes; for example, they cry in anticipation of pain upon seeing a doctor and needle a few months after getting an inoculation. Culture plays a role in the formation of scripts; for example, Utku Eskimos construe being alone as social isolation and feel loneliness, whereas Tahitians see being alone as an opportunity for spirits to cause uncanny feelings and fear. The intrafamilial environment is also important; for example, childhood patterns of relations with parents are significantly related to adult scripts about love relationships.
Research has shown that scripts facilitate processing of and memory for script-relevant information; provide inferences in the face of missing information; guide interpretation of ambiguous situations; promote script-confirming patterns of thought, emotion, and behavior; and are associated with individual differences in personality. Scripts can also have maladaptive consequences if applied when not relevant, leading to inappropriate inferences or recall. Scripts with problematic content can lead to maladaptive thinking, emotion, and behavior patterns associated with psychopathology. In general, scripts are more easily modified by experience when they are first being developed, but at a certain point they become resistant to change in the face of incongruent experience. Mildly inconsistent and peripheral information will be ignored or discounted; however, information that is highly inconsistent and highly central may undermine the script itself. For example, individuals who suffer a traumatic loss are often unable to sustain their construal of the world as meaningful. Methods for changing maladaptive scripts require more research, but one model of therapy proposes that the relationship between therapist and client under-mines a maladaptive interpersonal script by presenting recurrent experiences that are emotionally significant and substantially incongruent.

**SECESSION**

Secession is the act of withdrawing territory from a state and converting it into an independent state or joining it to another state. In the latter case, secession is combined with irredentism. Secession is a negative term, one that is more likely to be used by its opponents than its advocates. Supporters of secession prefer to describe themselves as struggling for something positive. For example, those who support Quebec’s secession from Canada describe themselves as “sovereigntists” or “independentists,” not as “secessionists.”

Secession can usefully be distinguished from three other terms with which it is often confused. First, it is not a synonym for “self-determination” but one form that a struggle for self-determination might take. Second, it is different, particularly in the minds of international lawyers, from “decolonization,” which involves the separation of a colony from its metropole, with a colony typically defined as a racially distinct territory separated from the metropole by saltwater and whose people do not enjoy metropolitan citizenship rights. Secession, by contrast, is seen as withdrawal from a state, with the territory involved usually a contiguous piece of the state’s territory or a nearby island. Third, secession is an act that is initiated and carried out by those who want a new state of their own. It should be distinguished, therefore, from “partition,” which implies the fresh division of a territory by an external (third-party) actor (O’Leary 2005). Irish nationalists sought the secession of Ireland from the United Kingdom, but the latter partitioned Ireland, as they later partitioned India and contributed to the partition of Palestine.

Secessions are generally attempted by minority nations that want their own state (or to be joined with another state), though Russia, with a significant majority of the state’s population, seceded from the Soviet Union. There is no prospect of immigrant ethnic groups, such as the Chinese community in British Columbia or the Koreans in California, seceding from their respective states, as these are not mobilized as nations. Nor is it foreordained that a minority nation will become secessionist. There is evidence that the timely accommodation of minority nations, involving territorial autonomy and, in the case of sizable minorities, inclusive power sharing (consociational) politics at the center, can reduce support for secession.

States almost invariably oppose secession. Many states explicitly rule it out in their constitutions. Some, such as Ukraine or Turkey, even make it impossible to change their constitutions to allow secession. In these cases, the unity of the state is a higher value than popular sovereignty. Americans need no reminders that states are often prepared to resist secession with considerable force, even if it costs many lives.

As international law is written by states, it is hardly surprising that its provisions on secession are very restric-
**Secession**

International law recognizes a legal right of “peoples” to “self-determination,” but this right was intended to apply only to historic European colonies, that is, to acts of decolonization. It was developed, moreover, at a time when significant numbers of acts of decolonization had already occurred. The right is a “once-only” right, to be exercised at the point of decolonization, and does not extend to minority regions within colonies or to minority or majority regions that intersect colonial frontiers. Oddly, then, the international legal right to “self-determination” is built on the constructs of imperialists. Since World War II (1939–1945), there has been only one clear example of a successful, internationally recognized secession that was opposed by the state’s authorities, the case of Bangladesh, which seceded from Pakistan with India’s help in 1971. With one questionable exception, all other secessions have either been agreed to by central authorities (East Timor, Eritrea, the Czech Republic and Slovakia) or have been recognized after central authority had collapsed (the fifteen republics that seceded from the Soviet Union). The Soviet Union’s republics had the additional advantage of a constitutional right to secession. The questionable exception is Yugoslavia. The secessions of Slovenia, Croatia, and Bosnia-Herzegovina were opposed by Belgrade (Serbia and Montenegro), but the Badinter Commission nonetheless ruled that Yugoslavia was in “a state of dissolution.” To bolster its case, the commission also cited a clause in the Yugoslav constitution that gave its republics the right of secession.

The unwillingness of the states system to sanction secession is underlined by a number of “de facto secessions” (Bahcheli, Bartmann, and Srebrnik 2004). Here, secessionist authorities have failed to win recognition from other states even though they have succeeded in monopolizing the sovereign functions of government on their territory, often for years or even decades. These regions include Transnistria (Moldova), Nagorno-Karabakh (Azerbaijan), Somaliland (Somalia), the Turkish Republic of North Cyprus (Cyprus), and Abkhazia and South Ossetia (Georgia). The strangest case of a de facto secession is Kosovo, which was liberated from Serbia’s control by an international military alliance in 1999. In spite of this, the international community has so far refused to recognize Kosovo’s independence. If it does, it is likely to do so in a way that does not set a precedent for others. It may help Kosovo’s case that, while it was not a full republic of the former Yugoslavia, it enjoyed equality with these republics within federal institutions and a similar level of autonomy. This may allow other states to argue that Kosovo is a special case, sufficiently like the full republics of the former Yugoslavia to enjoy similar rights.

While lawyers have debated the legal right to secession, philosophers have argued about the moral right. As liberals are committed to the idea of a legitimate state, it is difficult for them to rule out secession under any circumstances, although some suggest the priority should be to make the state legitimate, not to break it up. The two main liberal schools of thought on secession are based on “just-cause” and “choice” theories (Moore 1998). Just-cause theorists have traditionally taken a restrictive view of secession, arguing that a right to secede exists only when the state has been egregiously abusive. One of their most prominent representatives has recently offered a softer version of this: Minorities can secede if they are denied autonomy (Buchanan 2003). Choice theorists, using democratic arguments based on consent, analogize from marital to political divorce: Minorities should be able to leave if they want to and not just if they have been abused or not accommodated (e.g., Beran 1984).

Some scholars believe that states, particularly Western democracies like Canada and the United Kingdom, are becoming less resistant to secession and less likely to oppose it by force (Kymlicka 2001, pp. 387–393). In 1998, the Canadian Supreme Court established a process whereby a province can secede, providing there is clear support for breakup, and after negotiations with the federal authorities. The prime minister of the United Kingdom, John Major, opined in the early 1990s that Scotland could secede if it wanted to, and in the Belfast Agreement of 1998, London confirmed that Northern Ireland could join the Republic of Ireland, provided that this was approved by referendums in both jurisdictions. Ethiopia’s republics have also been given the right to secession, and recent peace settlements in Sudan and Papua New Guinea have extended this right to South Sudan and Bougainville, respectively. From the other side, one academic has argued that minorities, particularly in western Europe, are no longer as insistent on secession, provided they are given autonomy and are included in international (European Union) institutions (Keating 2001). Neither of these trends is universal. In most parts of the world, states are at least as insistent on maintaining unity as they ever were, and there are still many secessionist movements.

The record of secession as a method of conflict resolution has been mixed. In some cases, the transition from one state to two, or several, has been relatively smooth (Czechoslovakia, the Soviet Union, Norway/Sweden). In other cases, breakup had disastrous consequences (Yugoslavia, with respect to Croatia and Bosnia-Herzegovina, but so far not Slovenia or Macedonia). These contrasting cases suggest a straightforward point: Secessions that are opposed by the center and/or a significant community within the secessionist region are more likely to be violent (McGarry 1998).

Secrecy

Secrecy, according to sociologist Edward Shils, (1911–1995) is a form of concealment reinforced by sanctions against disclosure and differs from privacy in its non-voluntary character. In some societies, secrecy is concealment enforced by tacit and often religious proscriptions or taboos. In other societies, laws and statutes secure secrets and privileges for those who possess them. Regardless of how it is regulated, secrecy is implicated in the maintenance of religious or political hierarchies. Secrecy also plays an essential role in the internal division of groups by limiting access to knowledge.

In many instances, access to knowledge is regulated by membership associations or “secret societies.” Secret societies have been significant institutions in virtually all political cultures. For example, among the indigenous people of the Northwest Coast of North America, secret societies provided certain members of hereditary clans exclusive access to mythic, ritual, and political knowledge, which secured them against opposition from other clan members. Among many societies in Australia and Oceania, secret societies are associated with age grades and adult masculinity. Even when secret societies are open to all males, the societies must be entered through elaborate rites of initiation. Membership in such groups may then confer political and economic rights, as well as access to sacred or private historical knowledge.

In China, secret societies often emerged from mutual aid organizations, which represented and protected the interests of particular classes (peasant or aristocrat). Among the Straits Chinese in Southeast Asia, secret societies often worked to preserve language-based cultural traditions and mediated between diasporic and mainland groups, channeling resources and information between the groups. At various times, including revolutionary nationalist and communist wars, secret societies have provided crucial structures for organizing political activity.

Secret societies are associated both with the maintenance of legitimate power and the organization of oppositional movements. Insofar as secrecy is a principle that protects power, secrecy must both display itself and conceal the true nature of power’s exclusivity. In other words, political secrecy is public secrecy; people must be led to believe that there is something that they do not know, and that this something underwrites others’ power. Hence, secrecy is often associated with elaborate rituals and formalized communicational codes. This is true not only for the infamous sects of esoteric knowledge—such as the cults of Mithra in ancient Greece and the Rosicrucians and Masons or Opus Dei in the Christian tradition—but it also characterizes membership in contemporary political parties and groups such as the Ku Klux Klan in the United States.
Secrecy

The development of secrecy is intensified and accelerated in the context of the state, both in its pre-modern and its modern, bureaucratic forms. The idea that states should withhold knowledge from subjects on the grounds that it would harm them has a long history. This idea can be found in Plato’s Republic, book 2, where it is suggested that tales of gods warring with gods or performing immoral acts ought to be banned as the subject of poetry, lest these acts encourage similar behavior in humans. In City of God book 2, Augustine appraised the Christian church over the Pagan religions precisely because it claimed to oppose a politics of secrecy with a doctrine of universal truth. Nonetheless, state officials within the nations influenced by Christianity never relinquished the practice of secrecy as the basis of power—any more than did those inspired by other theologies.

Both the nature and theory of secrecy received impetus from the institutional and technological developments of modernity. In the nineteenth century, secrecy came to be thought of not only as a phenomenon within society but as an essential principle of social groups in general. German social theorist Georg Simmel (1858–1916) referred to secrecy as one of humanity’s “greatest achievements.” Simmel’s concept, on which Shils built his more elaborate definition, emphasized purposive aggression against a third person. According to Simmel, the concept and phenomenon of secrecy revealed society to be a formation based not on dyadic relations but on the spectral presence of the “third person.” By third person, he meant to encompass the total social formation, beyond those with whom one might have dialogic relations—including all those who precede one in history, and all who may come after, but especially those against whom one might forge an oppositional solidarity.

From Simmel’s perspective, the value of the secret is intensified by the possibility of its betrayal or revelation. Simmel also remarked that as societies become more complex, what is “public becomes ever more public, and what is private becomes ever more private.” A crucial development in this perspective is the emergence of writing and, more specifically, the epistolary form of letter writing, in which writing is linked to the idea of privacy. In the letter, the exclusion of others is simultaneously bureaucratized and made to appear as a necessary condition of interpersonal intimacy.

In German political economist and sociologist, Max Weber’s (1864–1920) writings, the link between bureaucracy and secrecy is both explicit and mutually sustaining. According to Weber, bureaucracies produce their relative superiority and claims on professional exclusivity by developing secret knowledge. Hence, while democratic capitalist societies generally presume and espouse the value of openness and transparency, they are increasingly subject to the force of secrecy. In his magisterial work, Economy and Society, Weber went so far as to claim that “the official secret is the specific invention of bureaucracy.” Weber also claimed that secrecy was doomed to fail, as the expert knowledge of private economic interest groups would ultimately come to supplant that of governmental elites.

Weber’s sense that government secrecy would ultimately give way to the regime of expert knowledge and, hence, corporate trade secrets has in some senses been realized to the extent that copyright and patent laws dominate the landscape of secrecy legislation. However, in recent years practices of state secrecy have expanded rather than diminished in the United States—despite the anticipation of state secrecy declining following the end of the cold war. (Similar developments have also been seen elsewhere.) According to the U.S. Information Security Oversight Office, acts of original classification (the secreting of primary documents, including “top secret,” “secret,” and “confidential” materials) decreased in 1995 by more than 36,000 to 167,840. However, that number increased to 258,633 by 2005. Moreover, derivative classifications, materials classified because they include citations of, or reference to, classified documents, increased at an even greater rate. In 1995, reported derivative classifications had decreased by almost 1.2 million to 3,411,665. In 2005, derivative classifications had grown to 13,948,140.

These figures reveal a general trend in the early twenty-first century of an increase in the production of state secrets and an expansion of their sphere of circulation. The latter fact, which derives largely from new digital technologies, enhances the aura of secrecy while the former consolidates the power derived from it.

The result is a doubled development. On the one hand, there are more secrets and more people who are aware that there are more secrets. On the other, fewer and fewer people are authorized to know the content of those secrets. Thus, in the United States, for example, the number of people who are authorized to know and determine the status of government knowledge decreased in the decade between 1995 and 2005 by about 26 percent.

Mitigating the U.S. trends of expanding state secrets are constitutionally authorized mechanisms for accessing information. These mechanisms include acts and procedures gathered together under the title of “Freedom of Information,” by which the press and members of the public are entitled to petition for the declassification of documents. The United States also legislates the mandatory termination of classificatory protections, through statutes of limitations on copyrights and patents, as well as limits on government classifications. The 1997 U.S. Senate’s Report of the Commission on Protecting and
Reducing Government Secrecy termed this built-in obsolescence of government secrecy the “life-cycle” of classification.

However, the legislated dissipation of secrecy protections is different from the mutual entailment of secrecy and revelation that Simmel had observed. Simmel was referring to the intensification of secrecy that comes about through the risk of its revelation. Such a logic can be seen in the transformation of military policies since 1993, when President William Jefferson Clinton signed Public Law 103-160, commonly known as “Don’t ask, don’t tell.” This law promised to limit surveillance activities directed against gays and lesbians in the U.S. armed forces, but it also prohibited people who have same-sex relations from serving in the military. The law also proscribes homosexual and bisexual people who are in the military from revealing their sexual orientation. In 1994 the policies emanating from the law resulted in 617 discharges. That number increased steadily, and in 2001, 1,273 people were dismissed from the armed services. Although dismissions on the basis of sexuality dropped as the U.S. government commenced war after 9/11, dismissions rose again in 2005.

Shils’s notion of the enforced secret reaches its apogee in the “Don’t ask, don’t tell” law. Moreover, the demand for the secreting of homosexuality in the military runs directly counter to the achievements of social movements over the course of the late twentieth century, at least in the Western nations. These movements had made sexual self-disclosure a foundational moment of self-liberation. Such achievements may have limited relevance in societies beyond the West. In the United States however, the logic of “Don’t ask, don’t tell,” appears to confirm Eve Kosofsky Sedgwick’s thesis, as articulated in The Epistemology of the Closet. Sedgwick states that in modern Western societies the epistemological basis of power operates, as it does elsewhere, in the vacillation between secrecy and revelation but in modernity becomes increasingly focused on questions of sexuality and, more specifically, on the differentiation of populations into hetero and homosexual types.

Inverting the historical relationship between secrecy and power, the “epistemology of the closet” and the policy of “Don’t ask, don’t tell” makes the possession of a secret (homosexuality) a risk and a source of disenfranchisement. That this inversion takes place while older systems linking secrecy and power are extended and intensified by new technologies of encryption, duplication, and dissimulation, reveals that the classical theories of secrecy are themselves in need of transformation.

SECULAR, SECULARISM, SECULARIZATION

The term secular arises from the history of Christianity and describes that which is not sacred or not of the church. The term secularization thus refers to the process by which human activity and knowledge progressively come under the control of scientific rather than religious understanding. Max Weber (1864–1920) termed this rationalization and intellectualization characteristic of modern times, “the disenchantment of the world” ([1918] 1946, p. 155).

This differentiating of the sacred from the secular is associated with Europe in the seventeenth century. Prior to this time in Europe, and in non-Western cultures generally, the sacred and the secular were not necessarily separate spheres in the context of political rule. Secularism is thus associated with modernity and in the twentieth century has come to refer to two interrelated practices: (1) a mode of political organization in which the state is neutral with reference to all established religions; and (2) later in
the century, a political practice of the state that protects the rights of minorities in a multicultural society.

The need to separate church from state arose in seventeenth-century Europe for three broad reasons: (1) the rise of the industrial bourgeoisie that questioned the divine right of kings, against the older landed feudal elites that drew on the political and economic power of the church; (2) the fatigue produced by a century of war in Europe, in which Christian denominations clashed with each other for political power; and (3) the challenge posed to religious knowledge by the great breakthroughs in science.

It is only in the late twentieth century that it became widely recognized that secular, secularism, and secularization are not neutral descriptive terms of universal applicability, but arise from a specific spatial-temporal context. Charles Taylor (1998), however, argues that despite its specific origins, secularism continues to be relevant for modern democracies everywhere. Even the most diversified societies can be secular, despite differences about religion at the deeper level, by building consensus on a “common political ethic,” such as a doctrine of human rights, freedom, and equality. Such a consensus can be brought about even if there is no agreement about the values in which this ethic is embedded.

From the latter half of the twentieth century, however, it is precisely the concepts of human rights, liberty, and equality that have been challenged as being (Western/Christian) culture-specific. The rise of modern political movements based on Islam offers a powerful challenge to the idea that modern societies must be built on the basis of separation between religious and political power. Even within the West, secularism as state neutrality is increasingly challenged by the growing diversity within these societies. It has become evident that, historically, “secularism” was achieved in Western societies only after defeating rival Christian denominations and diverse cultural practices. The religio-cultural formation that was victorious then attained the status of the “universal.” What we see today in the West then, is a resurgence of diversity rather than a new phenomenon.

In newer postcolonial democracies such as India, Hindu right-wing politics opposes the protection of minority rights that is an aspect of Indian secularism. A self-critical response from those opposed to such politics has been the acknowledgement that secularism in India has been state-centric and has not engaged sufficiently with beliefs and practices on the ground.

In this context arises the question of the relationship of secularism to democracy. Many contemporary states assume that secularism as a value trumps democracy. To take one instance, Turkey and France legally prohibit symbols of religion in public, over the protests of Muslim believers who want Muslim women to wear head scarves. Feminist scholars point out that the controversy centers on women’s bodies precisely because the patriarchal, patrilineal family is at the heart of modern statecraft. Veena Das suggests that once the idea of God was displaced, secular means had to be crafted to ensure that “the sovereign receives life beyond the lifetime of individual members” (2006, p. 94). In other words, Das suggests that the state has to reimagine its relation to the family in more complex ways than merely assigning the family to the realm of the private.

Samuel Huntington’s “clash of civilizations” thesis (1993) argues that current debates over secularism arise from the division of the world into opposing civilizational frameworks, broadly, that of the West and Islam. He traces the conflict between “Western” civilization and “Islamic” civilization to the founding of Islam itself. Thus what we see today is merely an “ancient rival” reacting irrationally to “our Judeo-Christian heritage” and “our secular present.”

From this point of view it appears that the contemporary “West” is rational and secular, with its religious heritage lying in the past, while contemporary “Islam” is irrational and trapped in religion. However, scholars have pointed out that the apparent secularism of Western states is built on Christian assumptions; for example, the practice of observing the weekly holiday on Sunday rather than any other day, is biblical in origin. Further, Western secularism involves the continuous regulation of what constitutes religious as opposed to nonreligious practices and institutions. In the United States, the legal apparatus of the state periodically defines what religion is by deciding whether particular forms of public behavior come under the principle of freedom of religion. In France, the antireligious state owns and administers all property belonging to institutions of religions that existed in France in 1905, when the law was passed.

The paradoxes of Western secularism are explained, in Talal Asad’s (2003) view, by the fact that the emergence of secularism in modern Europe merely shifted the proper domain of violence from religious communities to nation-states. Henceforth, the nation-state would determine the place of religion, and the only legitimate perpetrator of violence was to be the nation-state, whether the violence was inflicted upon its own citizens, upon other nations, or upon colonized parts of the world.

Ashis Nandy (1990) also makes the link between the violence of the modern nation-state and secularism. Despite its contradictions, the modern state has succeeded in marginalizing all religions, while its own ideologies of secularism, development, and nationalism act as intolerant faiths backed by the coercive state apparatus. Nandy recognizes “religious fundamentalism” (or in India, communalism), as a rational and modern project that seeks to control state power. Religious fundamentalism is thus a product of
“secularization” and is as intolerant of the eclecticism of lived religion as is the modern nation-state. A more tolerant society would require the recovery of those resources within religious practices that make it possible to live with “fluid definitions of the self,” an idea inimical to both modern state practices and to religious fundamentalism.

### SEEMINGLY UNRELATED REGRESSIONS

The seemingly unrelated regressions (SUR) model explains the variation of not just one dependent variable, as in the univariate multiple regression model, but the variation of a set of $m$ dependent variables; that is, the monthly consumption expenditures of $m$ consumers or the annual voting behavior of $m$ voters, in terms of the variation of general and specific input or independent variables and error terms specific to each individual, problems that are frequently encountered in many sciences. Indeed, John Geweke has written, “The seemingly unrelated regressions (SUR) model developed in Zellner (1962) is perhaps the most widely used econometric model after linear regressions. The reason is that it provides a simple and useful representation of systems of demand equations that arise in neoclassical static theories of producer and consumer behavior” (2003, p. 162).

It is the case that a SUR model is a collection of two or more regression relations that can be analyzed with data on the dependent and independent variables. For many years, the individual regression relations were fitted one by one, usually using least squares techniques and justified by an appeal to single equation estimation optimality properties; That is, the least squares estimators are best linear unbiased estimators according to the well-known Gauss Markov theorem and maximum likelihood estimators when single equation normal likelihood functions are employed. Also in traditional multivariate regression models with the same independent variables in each equation and normal error terms in different equations with zero means, different variances and non-zero covariances, it had been shown that applying the least squares method equation by equation leads to fully efficient maximum likelihood estimators for regression coefficients in different equations. What was overlooked in this pre-1962 literature is the fact that when the error terms in the different regression equations are correlated and different independent variables appear in the equations, the regression equations are related, not unrelated as many assumed incorrectly and hence the term “seemingly unrelated,” and that the sample information in other regressions can be employed to improve the precision of estimation of parameters in any given regression equation under a wide range of conditions. That is, new, operational SUR best linear unbiased estimators for the parameters of a set of say $m$ regression equations were put forward that uniformly dominate the single equation least squares estimators under a broad range of conditions.

It was shown that these SUR or generalized least squares (GLS) estimators are best linear unbiased and maximum likelihood and Bayesian estimators under frequently encountered conditions. In addition, by joint analysis of the set of regression equations rather than equation by equation analysis, more precise estimates and predictions are obtained that lead to better solutions to many applied problems; that is, portfolio formation procedures in 2003 work by Jose M. Quintana and colleagues, in which dynamic regression equations with time

---

*Nivedita Menon*
varying parameters and various input variables were employed to explain the variation of monthly stock prices. By taking account of the fact that the regression equations were related and not unrelated, SUR estimation, prediction, and portfolio formation procedures were utilized to yield improved analyses of the variation of stock prices and to form optimal portfolios with very good rates of return. In Arnold Zellner and Henri Theil’s 1962 work, similar techniques were applied to simultaneous equations models to yield a new joint estimator, the three-stage least squares estimator that dominates single equation estimators by taking account of the correlation of error terms in equations of the system by use of joint estimation of coefficients in equations of structural models.

The simplest version of a linear, constant parameter SUR system is one that contains \( m \geq 2 \) linear regression equations, \( y_i = X_i \beta_i + u_i, \ i = 1, 2, \ldots, m \), where \( y_i \) is an \( n \times 1 \) vector of observations on the \( i \)th dependent variable, \( X_i \) is an \( n \times k_i \) matrix with full column rank of observations on the \( k_i \) independent variables in the \( i \)th regression equation, \( \beta_i \) is a \( k_i \times 1 \) vector of regression parameters and \( u_i \) is an \( n \times 1 \) vector of zero mean error terms. The usual method of estimating the regression coefficients was to estimate the equations individually by least squares to obtain \( \hat{\beta}_i = (X_i'X_i)^{-1}X_i'y_i, \ i = 1, 2, \ldots, m \). However, in Zellner’s 1962 work it was shown that when the error terms are correlated across the equations, the equations are related and joint estimation, rather than equation-by-equation estimation, leads to more precise estimates of the regression coefficients and predictions of future values of the dependent variables. Indeed, as explained in the articles and texts cited in this entry’s bibliography, these joint SUR estimators are generalized best linear unbiased estimators and, with a normality assumption for the error terms, maximum likelihood and “diffuse prior” Bayesian estimators. Further they reduce to single equation least squares estimators when error terms in the different equations are mutually uncorrelated; that is, the equations are unrelated. In addition, use of SUR techniques leads to improved tests of hypotheses regarding regression coefficients’ and other parameters’ values.

Similarly, taking account of the error terms’ correlations across equations leads to better predictions of future values of the dependent variables, as shown in the 2005 work of Arnold Zellner and Guillermo Israilevich who use SUR techniques in forecasting U.S. economic sectors’ output growth rates and aggregate output growth rates. And in works of Sid Chib and Edward Greenberg (1995), John Geweke (2003), and Peter E. Rossi and colleagues (2005) modern Bayesian methods are described that yield optimal finite sample estimation, testing, and prediction techniques for many variants of the SUR model; that is, SUR models with time varying parameters and auto correlated error terms. Similarly, when the dependent variables are discrete random variables as in multivariate logit or probit models with correlated error terms, the SUR joint estimation, testing and prediction techniques have been found to be useful, as shown in the 1977 work of T. C. Lee and colleagues.

Segregation

Segregation is the practice of keeping racial and ethnic groups separated. This includes, but is not limited to, the separation of racial groups in schools, housing, public facilities, and public transportation. This separation usually involves a dominant racial-ethnic group discriminating against a subordinate racial-ethnic group, as in the U.S. South during legal segregation.

The system of legal segregation in the U.S. South was a totalitarian social system that Southern whites developed and maintained after the abolishment of slavery in 1865. The primary function was to continue the social system of servitude, the racial caste hierarchy, and the economic control of African Americans under the legal fiction of separate but equal. Legal and informal segregation practices (Jim Crow) meant comprehensive racial subordination and imposed a badge of degradation on all African Americans in many areas of the United States. The daily practice of legal segregation is “a compulsory ritual denoting first and second-class citizenship.” It has more than psychological and social significance, serving also the basic economic and political purpose of facilitating the exploitation of nonwhites by whites, collectively and individually (Kennedy 1959, p. 206).

Challengers of Segregation

The social system of legal segregation began in the late 1870s and 1880s, and there were several attempts by African Americans to challenge the laws, the violence, and the inequality that resulted from their implementation. The first challenge began with the U.S. Supreme Court case of Homer Plessy, an African American man, who refused to sit in the colored section on a train. His case went to the Supreme Court in 1896. As a result of that case, the laws of racial segregation were buttressed. The decision stipulated that laws mandating segregated areas and sections for blacks and whites, in theory, could be separate but equal.

In 1954, Thurgood Marshall, at the time a successful black attorney for the National Association for the Advancement of Colored People (NAACP) and later U.S. Supreme Court justice, won the Brown vs. Board of Education case before the U.S. Supreme Court; the case ostensibly ended segregation in public schools. However, the laws of segregation did not come to an official end until the enactment of the Civil Rights Act in 1964. This act resulted in large part from the nonviolent civil disobedience of the black-led civil rights movement from the 1950s to the 1970s, which included minister-leaders such as Dr. Martin Luther King Jr.

Dr. King, famous for his “I Have A Dream” speech against segregation given at the Lincoln Memorial in Washington, D.C., in 1963, led the Montgomery bus boycott. Rosa Parks (1913–2005), a member of the NAACP, was arrested for refusing to give up her seat to a white man on a segregated bus. Over decades a great many African Americans, including leaders and intellectuals such as Parks, King, Marshall, Malcolm X, W. E. B. Du Bois, and Ida B. Wells-Barnett, stood up against the injustices of segregation, lynching, and civil rights violations.

Contemporary Issues of Segregation

Even though the official segregation system was finally outlawed by the 1968 Civil Rights Act, its reality and impact continue into the twenty-first century. The racial attitudes of whites on surveys since found that ever fewer whites publicly subscribe to the earlier views of the Jim Crow era. Nevertheless, segregated schools, neighborhoods, and churches are still prevalent. In the early twenty-first century, the United States remains racially segregated and racial equality remains more of an ideal than a reality.

The continued spatial isolation and segregation of black Americans have been achieved by a conjunction of racist attitudes, covert and overt discriminatory behaviors, and rooted institutional practices that continue to subordinate black Americans in most institutions. Social scientists have shown the serious repercussions of this for blacks and other Americans.

Social science research has also shown that racial segregation in housing and education still adversely affects the health of African Americans and other Americans of color because that segregation helps to reinforce institutional segregation in yet other institutional areas. Economic inequality is closely linked to racial inequality,

Arnold Zellner

SEGA

See Video games.

Segregation

and both operate as strong determinants of major variations in health status.

Although other subordinated racial groups such as Latinos and Asian Americans, as well as some white ethnic groups, have experienced imposed residential segregation in U.S. history, no group has experienced the high degree of segregation and isolation faced by African Americans, “who are twice as isolated as Hispanics and Asians and about 60% more segregated” (Massey and Denton 1993, p. 67). The social, health, and economic repercussions of this residential segregation are similar to the detrimental results experienced by black South Africans in South Africa’s dismantled oppressive system of apartheid.

SOUTH AFRICAN APARTHEID

The oppressive system of apartheid swept through South Africa as a consequence of the electoral victory of the white-racist National Party in 1948. Apartheid embraced a totalitarian racial policy essential to replace the old policy of informal segregation. Legal apartheid controlled and manipulated the space in which black people developed their lives and livelihoods. The main aim of apartheid was total separation of blacks and whites in schools, hospitals, beaches, stores, buses, and housing. Black South Africans were forced to live in subordinate conditions, were separated from their families, were subjected to physical and psychological trauma, and were forced to carry identification cards to move about their country. The white South African government forced black South Africans to live in particular areas called Bantustans and townships. The townships consisted of deplorable one-room shanty houses made of cardboard and scrap metal. Entire families lived in these shanty houses without running water and electricity. These deplorable conditions still exist into the twenty-first century in South Africa. The system of racial apartheid, for many decades during the twentieth century, disproportionately placed all economic, social, and political power in the hands of whites, at the expense of every other racial-ethnic group.

The experiences of apartheid in South Africa for blacks were not unique. The institutionalization of racism there, a process that permeated and perverted every aspect of the individual and collective lives of South Africans, was similar in many aspects to that of the era of legal segregation in the United States. In the early twenty-first century both still have a striking persistence of residential segregation and other racial inequalities in regard to socioeconomic, health, political, and educational resources. South Africa’s history of racial, cultural, and economic tensions still affects black South Africans who were used as a cheap source of labor and who were prevented from purchasing land, voting, and interracial marriage.

Black South Africans resisted the system of apartheid just as African Americans resisted legal segregation. Nelson Mandela, an internationally recognized leader in the struggle for black civil rights, was the head of the African National Congress, whose struggle played a major role in finally dismantling racial apartheid. Mandela was imprisoned in 1963 for his participation in the fight for civil rights, and he spent nearly thirty years of his life in prison. He was released in 1990 and served as president of South Africa from 1994 to 1999. His contributions, accomplishments, sacrifices, and commitment to and for civil rights are recognized and celebrated internationally.

Unlike the United States, South Africa was forced to create the Truth and Reconciliation Commission, with the power to interview white oppressors and their victims, to establish historical documents of the events, to unearth the missing dead, and to grant amnesty, in order to secure a democratic society in South Africa. Mandela’s message of truth, justice, equality, and reconciliation dominated the early days of transition and aided in the success of ending the oppressive system of apartheid. In contrast, neither the U.S. government nor state governments have ever apologized for the enslavement and segregation of African Americans. A truth and reconciliation commission whose work would recognize that history of racial oppression might do for the United States what it did for South Africa.

SEGREGATION, OCCUPATIONAL

SEE Crowding Hypothesis.

SEGREGATION, RESIDENTIAL

Residential segregation refers to differences among social groups in their spatial distribution. Conceived broadly, the topic subsumes regional and other macro-level patterns of spatial distribution; but the research literature has focused primarily on group differences in distribution across neighborhoods in urban areas. Research on residential segregation constitutes one of the oldest traditions in sociology and has a rich history of cumulative development extending back to the founding of the discipline. Patterns of neighborhood distribution received close attention in W. E. B. Du Bois’s *The Philadelphia Negro* (1899), a landmark work often viewed as the first major empirical study in urban sociology. Studies of segregation processes of neighborhood change were integral to the Chicago School tradition spawned by Robert Park and Ernest Burgess’s *The City* (1925) and were a mainstay of empirical urban sociology in the 1920s, 1930s, and 1940s.

Residential segregation occurs along many lines of demarcation in social life. Segregation is most pronounced on the dimensions of race and ethnicity and socioeconomic status but is also observed in lesser degrees along cultural and religious lines, stage of family-life cycle, and differences in lifestyle. As a result, cities can be described as urban mosaics of heterogeneous neighborhoods marked by relative internal homogeneity in social characteristics. Urban ethnographies identify a multitude of neighborhood types—“old money” elite enclaves, “nouveau riche” gated communities, suburban developments, working-class areas, ethnic villages, areas of immigrant settlement, poverty areas, gay and lesbian districts, artist colonies, and so on—and they document the variation in social life across these areas. Urban theory outlines the micro- and macro-level dynamics involved. Quantitative studies describe the extent to which social differentiation is expressed spatially and assess the impact of the various factors shaping segregation trends and underlying neighborhood change. The literature on racial and ethnic segregation and segregation among socioeconomic groups is especially well developed and establishes that these forms of segregation are maintained both by informal and decentralized social dynamics and by structured institutional forces, including legal and regulatory guidelines.
In the United States the most closely studied aspect of segregation is the white–black residential color line. Historically, white–black segregation has been, and remains, more pronounced than any other form. For most of the twentieth century it was maintained by a web of interlocking laws, regulations, and institutional practices supplemented by intimidation and violence on the part of whites, which in combination functioned to exclude blacks from white residential areas. The separate-but-equal doctrine established by the Plessy v. Ferguson Supreme Court decision of 1896 provided the legal bulwark for the oppressive Jim Crow system in the South that formally separated blacks and whites in schools and public facilities. In the North and Midwest, restrictive covenants, realtor discrimination, so-called mortgage redlining, and related institutional practices combined with informal intimidation and violence by whites to foster levels of white–black segregation and black ghettoization that surpassed even the levels seen in the South. This unparalleled pattern of segregation had severe consequences for African Americans: inferior housing and schooling, sharply restricted life chances, and disproportional exposure to concentrated poverty and attendant social problems such as drug abuse, crime, and gang violence. In short, the residential color line has been at the heart of the extreme social isolation and disadvantage experienced by the African American population in the United States.

The Civil Rights era of the 1960s, following on crucial legal decisions from the 1950s and earlier (e.g., the Supreme Court Brown v. Board of Education of Topeka in 1954), brought the dismantling of overt, formal mechanisms of white–black segregation. Initially, change was often more symbolic than consequential. For example, the Fair Housing Act (Title VIII of the Civil Rights Act of 1968) swept aside many practices of overt housing discrimination in principle but in practice was not backed with effective enforcement policies. Effective enforcement of antidiscrimination policy came only with later legislation (e.g., the Fair Housing Amendments Act of 1988) and associated court rulings. Decades later, reductions in housing discrimination, especially the more blatant formally sanctioned practices, became clear. But discriminatory practices have endured in both the informal realm and less obvious institutional practices (e.g., siting of low-income housing). Consequently, changes in residential segregation have been slow in coming despite seemingly sweeping legal reforms. This is evident in patterns of resurging racial segregation in public schools, as documented by Gary Orfield (2001), which is rooted in enduring patterns of racial residential segregation.

The white–black color line presents a special case for segregation theory. Segregation patterns for other ethnic and racial groups in the United States have not involved comparable levels of social isolation and residential disadvantage. Similarly, patterns of residential assimilation observed over time for many other ethnic and racial groups have not been seen for African Americans. To be sure, white–black segregation has not been a constant. It increased, rising from moderate to unprecedented high levels during the era of the Great Migration of African Americans to northern urban areas during the early part of the twentieth century. In 1970, after a half-century of stasis, white–black segregation began slowly declining and by 2000 had returned to levels not previously seen since 1920–1930; this trend has been accompanied by a rapid disappearance of exclusively white residential areas, as shown by Glaeser and Vigdor (2003). Variation in white–black segregation across metropolitan areas also should be noted; generally, segregation is higher in metropolitan areas that were major destination sites of the Great Migration (e.g., Chicago, Cleveland, Detroit, Philadelphia) and lower in metropolitan areas of the South and West that rose to national prominence after World War II (e.g., Houston, Los Angeles, and San Diego). The trends over time and the variation across metropolitan areas are both important. But the key social fact is that white–black segregation remains more pronounced than any other form of segregation. It is quantitatively more severe and, in a pattern not typically seen for other groups, is routinely manifest on multiple dimensions (e.g., uneven distribution, isolation, clustering, concentration, and centralization) simultaneously, a phenomenon observers such as Massey and Denton (1989) characterize as hypersegregation.

White–black residential segregation is also exceptional for the near absence of dynamics of spatial assimilation. Residential segregation of earlier European immigrant groups dissipated slowly over generations as reductions in cultural and socioeconomic differences between groups were accompanied by steady reductions in spatial separation from “old stock” European groups. At the start of the twenty-first century, a similar dynamic appears to be operating for Latino and especially Asian immigrant groups. As Massey (1985) notes, a comparable process has yet to be observed for African Americans. Thus, for example, the rapid suburbanization of the African American population since the 1980s has largely extended white–black segregation to suburban areas rather than fundamentally reducing overall segregation as historically occurred for other groups.

The reasons for enduring high levels of white–black segregation in the post-Civil Rights era are the subject of much consideration. Scholars generally concur that contemporary white–black segregation cannot be explained as a byproduct of economic segregation and group differences in income. In contrast to patterns observed for other groups, segregation among whites and blacks of similar
socioeconomic status is scarcely lower than overall white–black segregation. In view of this fact, future research will need to monitor the residential experiences of potential bellwether groups such as middle- and high-status African American households. There also is widespread consensus that racial discrimination continues to be a major factor in contemporary white–black segregation. Most observers, as reported by Massey and Denton (1993) and Margery Turner and colleagues (2002), conclude that blatant forms of exclusionary discrimination have declined; but many, as also reported by Massey and Denton (1993) as well as John Yinger (1995), conclude that less obvious but highly consequential forms of discrimination continue.

Opinion is mixed regarding the relevance of informal residential dynamics outside the purview of existing antidiscrimination law. As Camille Charles (2001) has shown, blacks encounter higher levels of negative stereotyping and prejudice and rank at the bottom in survey responses regarding preferences for potential neighbors. Scholars such as John Yinger (1995) and DouglasMassey and Nancy Denton (1993) discount the role of prejudice in the absence of discrimination, but studies by Thomas Schelling (1978), William Clark (1991, 1992, 2002), Mark Fossett (2006), and Fossett and Warren Waren (2005) suggest that household location decisions governed by such preferences can sustain high levels of segregation even in the absence of discrimination. Consistent with this view, studies of residential movement, such as Ingrid Ellen’s (2000), indicate that avoidance of blacks on the part of whites and other groups—a social dynamic outside the scope of existing antidiscrimination law—is an important contributing factor in maintaining segregation. This suggests that significant movement toward residential integration for African Americans will not be observed until greater declines occur in negative stereotyping and prejudice against blacks as well as in exclusionary housing discrimination against blacks.

SEGREGATION, SCHOOL

Education has been long considered integral to the social health of most nation-states. Despite this regard for its importance, particularly with respect to the frequent promise of education as a “great equalizer,” schooling has often been used by dominant groups to engage larger systems of oppression. Indeed, the long and pervasive histories of school segregation that characterize many nations remain glaring proof of such inequities in educational justice.

APARTHEID SOUTH AFRICA

In apartheid South Africa, school segregation was used as one government-directed means to perpetuate racial inequality. The Bantu Education Act of 1953, which gave the state control of all schools, was one of many legislative acts that sought to remove and restrict the lives of non-whites in every possible sphere of life. While schooling for black Africans dramatically expanded under apartheid, this seemingly paradoxical effect was driven by the survival need of the white Afrikaner regime to acculturate the majority black population to the ideological beliefs undergirding apartheid segregation, as well as to limited job horizons, in an effort to both protect white skilled labor from African competition and provide masses of unskilled labor for growing white industry. As Nelson Mandela recounted in his autobiography Long Walk to Freedom (1994), this form of education amounted to “intellectual ‘basskap’ (domination), a way of institutionalizing inferiority” (p. 145).

Aside from its ideological destructiveness, the segregated schooling imposed through Bantu Education was characterized by a highly inequitable distribution of resources leading to overcrowding, poor facilities, and low-grade teachers. The inequitable conditions institutionalized through Bantu Education would eventually backfire on the Afrikaner regime, as black youth entering their late teens and early twenties “rose up with a vehemence,” most notably during the Soweto student uprising of 1976 (Mandela 1994, p. 148).

RACIAL SEGREGATION IN THE UNITED STATES

Tracing the historical progression of school segregation in the United States provides another striking example of the way education becomes incorporated into a system of oppression. In 2002 Peter Irons verified that never has there been a year in U.S. history when even half the country’s black children attended schools where a majority of children was white. However, school segregation in the United States exists as but one part of a centuries-old, interconnected system of racial oppression. As Joe Feagin has documented, the white male founders who drafted the U.S. Constitution built into the country’s foundation mechanisms designed to maintain African American enslavement. Eight decades would pass before these enslavement mechanisms were removed. Following a short Reconstruction era in the South, during which time public educational opportunities were finally extended to newly freed black Americans (as well as poor whites), the southern white elite, predominantly former slaveholders returning to power, quickly imposed extreme racial segregation as a new form of domination.

In the post-Reconstruction era, African Americans in the North were not exempt from the effects of a broadening racial segregation. There the daily life of black Americans was impacted by an informal de facto segregation, which affected black children’s education as well.

Mark Fossett
Throughout the South, however, where the majority of African Americans lived, segregation became a deeply entrenched way of life, endorsed by law and culture. Legal segregation, called Jim Crow, was a totalitarian system of government-buttressed control that extended to virtually every facet of life. Under the system of legal segregation African Americans faced not only large-scale discrimination by whites in the economy but also met severe restrictions in access to education, housing, political participation, churches, health care, and public accommodations. Indeed, the hand of overt segregation was undergirded by the constant threat of white violence and extended to every corner of lived existence for African Americans, limiting even the cemeteries where one could be interred.

Nowhere was the existence of legal segregation more rampant than in U.S. school systems. With few exceptions, public and private educational institutions—from nursery schools to universities—were segregated in the South. Segregation in schools, as in other institutions, was legally protected, indeed required, by court decisions, climaxing most significantly in Plessy v. Ferguson. This 1896 Supreme Court decision upheld the legal mandate for segregated public accommodations and set the infamous “separate but equal” legal precedent. This separate-but-equal standard was a backhanded way to seemingly satisfy the Fourteenth Amendment equal protection clause while paving the way for segregated schooling that ended up being far from “equal” for African Americans.

In practice, southern state and local governments disregarded the education of black youth. As Paul Finkelman stressed, “the disparity in public expenditures guaranteed that blacks would have inferior educational facilities” (2004, p. 45). In 2004 Richard Kluger documented how such disparities operated during legal segregation, with the case of Clarendon County, South Carolina. In 1949 that county government paid $179 per white pupil, while spending only $43 per black pupil there. In this same year the county’s 2,375 white children went to twelve different schools, valued at $673,850 (an average value of $56,154 per building); the county’s 6,351 black students were dispersed over 61 schools, collectively valued at $194,575 (an average value of $3,190 per building). Many schools were dilapidated, lacking modern heating or indoor plumbing. The racial disparity in spending meant significantly larger class sizes for black students and poorer pay for black principals, supervisors, and teachers. These material inequities served to support the supremacist doctrine that whites intended to communicate through segregation’s practice: Whites and blacks are not simply different; whites are superior.

Significantly, black parents and activists have engaged in long struggles for adequate and desegregated schooling since the mid-nineteenth century. They frequently met extreme resistance and were largely legally stifled in their efforts until the period from 1930 to 1950, when successful court cases (most brought by the National Association for the Advancement of Colored People [NAACP], founded in 1909) laid the legal foundation for what Finkelman referred to as “the watershed decision of the twentieth century” (2004, p. 35), Brown v. Board of Education (1954). As Feagin and Bernice McNair Barnett noted in 2004, the Supreme Court decision in Brown effectively dethroned the Plessy v. Ferguson doctrine of separate-but-equal that had defined the law, striking down segregation in schooling with the following declaration by the justices: “We conclude that in the field of public education the doctrine of ‘separate but equal’ has no place. Separate educational facilities are inherently unequal.”

Brown was a landmark decision because it was interpreted by numerous judges as a mandate to dismantle state-created segregation in all major institutions, and recognized African Americans as first-class citizens. As T. Alexander Aleinikoff maintained, in Brown “segregation in the public schools is condemned for producing second-class citizenship for African-Americans both because it imposed a stigma on them (as persons not fit to go to school with whites) and because it did not adequately prepare them to be effective citizens” (2002, p. 40).

The reaction to Brown by the southern white elite and public ran from general hostility to massive resistance, and few schools were actually desegregated for more than a decade. One of the primary reasons for the failure was the weakness of the 1955 companion case, Brown v. Board of Education (Brown II), which vaguely stipulated that desegregation should proceed “with all deliberate speed.” White leaders, including President Dwight Eisenhower, failed to back the Court’s decrees with federal authority. Additionally, some state governments passed laws in an attempt to “bypass” the decrees, for example, by issuing grants or tax credits to white families to send their children to segregated private schools, where Brown’s reach did not extend. Not until the late 1960s did the Supreme Court and other federal courts finally force meaningful school desegregation in the South.

RESEGREGATION IN THE POST-
BROWN ERA

Studies examining African American academic achievement document the substantial benefits of desegregated schooling for children of color. Reviewing desegregation’s impact, in 2004 Janet Ward Schofield and Leslie R. M. Hausmann found desegregation positively impacted high school graduation rates and black academic achievement. The impact extends beyond primary and secondary schooling, such that African Americans attending inte-
grated schools are more likely to attend college, entertain higher occupational aspirations, gain access to beneficial networks, and acquire better jobs. It is important to note, however, that such positive outcomes are less influenced by the actual racial heterogeneity of desegregated schools than they are by the typically better educational infrastructure that exists in such schools, for example, in terms of resources. In other words, the great crisis of segregated education has not been that children of color cannot be as well educated aside other children of color, but rather that segregated educational institutions have been and most often continue to be, as Brown reminds, “inherently unequal.”

A number of scholars and civil rights advocates have argued for the importance of integrated education, particularly as a way to reduce racial isolation. Participating in diverse educational communities, all students become better prepared to live, learn, work, and participate democratically in an increasingly multiracial world. Additionally, school desegregation creates opportunities to break down stereotypes as students associate with those unlike themselves. Individuals who attended desegregated schools are more likely to live and work in integrated settings, weakening overall racial isolation.

Despite significant progress, by the late 1970s many white liberals began backtracking in their commitment to desegregate U.S. schools. By the 1980s, such backtracking was widespread, primarily as a result of new conservative presidential administrations and courts. Through the 1990s courts allowed many school systems to abandon desegregation plans. Notably, Supreme Court decisions in Board of Education v. Dowell (1991), Freeman v. Pitts (1992), and Missouri v. Jenkins (1995) proved damaging to long-term desegregation, ending federal segregation orders before lasting success could be demonstrated in the interest of returning schools to local white control. In 2004, Lia B. Epperson identified the fault of this local-rights approach, arguing that “It is a standard that treats whites and blacks as if they were similarly situated and ignores the history of segregation and its vestiges…. This very form of local control allowed segregation to flourish in the era before Brown, and has done so again in the decade since these decisions” (2004, p. 140).

As Jonathan Kozol attested in 2005, retreat in desegregation has allowed for the persistence of already segregated schools, as well as the rapidly growing resegregation of schools that had been integrated. The Harvard Civil Rights Project reported in 2003 that three-fourths of black and Latino students attended predominantly minority schools, and more than 2 million attended “apartheid schools” where 99 to 100 percent of students were not white. As during legal segregation, racial disparities in per-pupil spending remain extreme.

Even within schools integrated at the facility level, a type of “second-generation segregation” is often imposed through the racially correlated allocation of educational opportunities. For instance, many scholars argue that ability tracking (a practice instituted soon after the Brown decision) has led to the emergence of what economist William Darity Jr. refers to as “segregated curriculums.” Beginning as early as elementary school, tracking frequently creates an internal racial segregation, as students of color are disproportionately assigned to lower academic tracks and are relatively absent from accelerated tracks (e.g., “gifted” or honors programs). In 2002 Terence Fitzgerald additionally uncovered categorical labeling practices whereby African American students were disproportionately assigned to special education and/or behavioral disordered categories, as well as more frequently expelled or placed in alternative school settings. The effects of such racially stratified practices have far reaching consequences, initiating a discriminatory cycle of restricted educational opportunities for students of color that leads to inferior learning opportunities, diminished school achievement, oppositional responses, and exacerbated racial disparities in school.

As the increasing prevalence of resegregation and second-generation segregation displays, and as Feagin and Barnett urge, efforts to end racial segregation require “constant renewal, for established arrangements of centuries have a strong social inertia” (2004, p. 1104). Beyond the U.S. and South African legacies, school segregation targeting ethnic or cultural minorities has been documented in many other nations, including England, the Czech Republic, Hungary, Bosnia, and Croatia. Only with continued resistance to the de facto segregation of schools around the globe, acknowledgement of the benefits of integrated education for all, and renewed commitment to actions that will ensure more equitable, integrated societies, can the promise of education be fulfilled.

Selection Bias

An important aspect of empirical investigations in the social sciences is to draw inferences for the whole population of interest when one has data only on a subsample from that population. A first step in conducting such inference is to assume that the subsample under examination is drawn randomly from the population. However, in many instances in economics, or in the social sciences in general, it is not possible to make such an assumption. For example, suppose one is interested in drawing inferences regarding the determinants of wages for women when one has information on wages only for women working in market employment. If the sample of market-employed women “differs” from the population in some systematic way, then using the sample of employed women may lead to incorrect inferences regarding the determinants for all women. This issue, where the inference based on subsample is not appropriate for the entire population, is known as selection bias.

The example of employed women is useful for further illustrating the concept of selection bias. In fact, the original papers on selection bias were motivated by empirical work on precisely this topic. Suppose one has a sample of women of which, without loss of generality, half are...
Selection Bias Regression

employed in market employment and half are not. Furthermore, suppose each woman is characterized by observable characteristics, such as race, age, and education, and unobservable characteristics, such as motivation and ability. Also assume that these unobservable characteristics are uncorrelated with the observable characteristics so as to demonstrate that selection bias arises even with exogenous conditioning variables. Suppose the objective of the researcher is to explore the relationship between the observable characteristics and wages for all women by using only the data on the subsample of workers.

First assume that the decision to work in market employment is random. That is, each individual tosses a coin and on the basis of the coin toss decides whether or not to work. In this case examining the subsample leads to correct inferences because the process of selection for the sample, which is used to draw inferences, is random; thus there are no differences between the employed sample and the nonemployed sample. As a result there is no selection bias.

Second, now suppose that only the highly educated individuals in the population are observed to be working in market employment. In this case the working sample would be overrepresented by individuals with higher levels of education. Thus, the sample of employed workers will have different average characteristics from those observed to be not working in market employment.

However, since the topic of interest is how the individual’s characteristics affect wages, one can control for the role of any observable characteristics when performing estimation over the employed sample. Thus differences in observable characteristics alone will not lead to selection bias.

Finally, consider the case in which all the highly motivated individuals in the sample of women are those that are observed to work in market employment. If motivation affected only the decision to be employed but not the wage, then this would not induce selection bias; even though the sample of working women would have a higher level of motivation on average than the whole population, one could still directly control for all the determinants of wages when examining the relationship between these determinants and wages. However, consider a case in which motivation does affect wages as well as the market work decision. In this case, the sample of employed women would have wages that were determined by the observable characteristics, which one could control for, and their level of motivation, which one could not control for. Moreover, as one has only a sample of motivated individuals working, one must conclude that for this employed sample the role of motivation, on average, is to increase wages. Failure to account for the role of motivation leads to a selection bias and incorrect inferences regarding the determinants of wages. Thus, in general, selection bias occurs when the unobservable features determining the probability of being observed in the subsample used for inference (in this example the sample of employed women) are correlated with the unobservables determining the outcome of primary interest (i.e., wages).

The issue of selection bias arises in a large number of empirical investigations in economics. Accounting for selection bias has therefore become a critical feature of empirical work in economics. One can see from the example above that adjusting for selection bias essentially requires controlling for the role of the unobservables. The first efforts to account for selection bias were conducted in a fully parametric setting. That is, the distribution of all the unobservables in the model were fully stated up to unknown parameters. This approach was suggested by James J. Heckman (1974, 1979) and ever since has had a substantial impact on both theoretical and empirical microeconometrics. Subsequent theoretical and empirical work in this area focused on relaxing the distributional assumptions in the model and thus attempted to make inference more robust to the assumptions employed in the earliest investigations. The 1998 article by Francis Vella surveys these departures from the original Heckman formulation and treatment. Another important innovation, as discussed by Charles Manski’s 1989 article, has been the use of bounds in this literature. According to this approach, one attempts to infer the upper and lower bounds on the object of interest (for example, the impact determinants of wages) when one relaxes various assumptions underlying the process determining selection bias.

SELECTION BIAS REGRESSION

SEE Heckman Selection Correction Procedure.
SELECTIVE ATTENTION

Selective attention involves the ability to attend to relevant information while ignoring irrelevant information. In early research on this topic, a critical question was whether attention occurs before (early selection) or after (late selection) the information is processed for meaning. One of the tasks used to answer this question is the dichotic listening task. In this task, participants listen to different passages of text presented in each ear through headphones. Researchers found that when questioned about the message in the unattended or ignored ear, participants detected changes in perceptual characteristics (e.g., pitch, volume) but did not notice other meaning-based changes. This result suggests the existence of a perceptual filter that selects information based on features such as volume or pitch. This filter serves to limit the amount of information entering short-term memory (i.e., the “bottleneck” in processing). However, other evidence suggests that unattended information also passes through the filter, though at an attenuated level, whereas still other results suggest that attention occurs much later, after all information has been processed for meaning. One current model of selective attention proposes that attention can occur early or late, depending on the perceptual and memory demands imposed by the task.

Selective attention is also investigated employing tasks using reaction time, measured in milliseconds, as the variable of interest. In the Stroop task, participants name the color of the ink in which a word is printed. Individuals are slower to respond in an incongruent condition (e.g., the word red printed in green ink) compared to a congruent condition (e.g., the word red printed in red ink), because the relatively automatic word-naming response must be inhibited in the incongruent condition. This interference is more pronounced with increased age, even in relatively healthy older adults. In visual search tasks, participants identify a target item among irrelevant distractor items. Under difficult conditions, when distractors are physically similar to the target, search becomes less efficient, particularly for older adults. However, under conditions in which the target is a unique item and tends to “pop out” from the distractors, search performance is comparable for younger and older adults. Using these tasks with brain-imaging techniques has allowed researchers to identify a frontoparietal network of brain regions involved in selective attention. Healthy older adults show increased activations, compared to younger adults, in this frontoparietal network, combined with decreased activations in visual cortical regions. The increased activation may serve as a compensatory mechanism for age-related declines in visual processing.

Other causes of individual differences in selective attention include attention deficit hyperactivity disorder (ADHD), which has typically been associated with global deficits in attention. However, recent research using visual search tasks suggests no differential impairment in selective attention between ADHD children and matched control children, although ADHD-related deficits have been observed in other components of attention, such as the ability to switch between two different tasks. Although there is little evidence of sex differences in selective attention, a few studies using the dichotic listening and visual search tasks have found moderate differences in selective attention favoring women.

SELECTIVE SERVICE

During major military conflicts in which the United States has been involved throughout its history, the government has utilized various programs and forms of military conscription in order to draft male citizens to the armed forces. While no draft has been in place since 1973, the Selective Service exists as an independent agency within the federal government to administer the registration of eighteen-year-old males, which is required by law, and conduct a draft should a need for military manpower over and above a volunteer force arise. An individual who is appointed by the president of the United States and confirmed by the U.S. Senate directs the Selective Service System.

HISTORICAL PERSPECTIVE

Congress passed the first military conscription act on March 3, 1863, during the Civil War. The act authorized President Abraham Lincoln (1809–1865) to draft men between the ages of twenty and forty-five into military service for the Union forces. The law, which included the option of draftees to pay a commutation fee of $300 to escape enlistment, provoked protests in New York City by those who saw it as unfairly protecting the wealthy.
Lincoln was forced to send federal troops to quell violent mobs. The Confederate States also instituted conscription in 1862, and it proved just as unpopular in the South as in the North. The next military draft law in the United States was passed in 1917; the Selective Service Act gave the president the power to conscript men for service during World War I.

As American involvement in World War II approached, President Franklin D. Roosevelt (1882–1945) signed the Selective Training and Service Act of 1940. This act created the first peacetime draft and established the Selective Service as an independent federal agency. The original legislation called for a service commitment of twelve months but was expanded to eighteen months following direct U.S. engagement in hostilities. Men between the ages of eighteen and forty-five who registered with the Selective Service were eligible to be inducted into the army and Marine Corps, and more than 10,000,000 men were inducted between 1940 and 1947. New legislation in 1948 reduced the mandatory registration age range to between eighteen and twenty-six. Military conscription continued during the Korean War in the 1950s and, most notably and controversially, during the Vietnam War.

Beginning in 1964, President Lyndon B. Johnson (1908–1973) was authorized by Congress to increase the number of troops in Vietnam, and by early 1968 the United States had more than 500,000 troops there. Tens of thousands of young men were drafted through the Selective Service lottery, while thousands of others avoided service through exemptions—also called deferments—granted by the several regional Selective Service draft boards around the nation based on educational commitments, membership in the clergy, medical restrictions, membership in the National Guard, and other obligations. Critics of the draft process noted an inordinate number of minorities had been selected, and questioned the randomness of the lottery. As in the past, the draft was seen as unfairly singling out those without the economic means to avoid service. As the number of U.S. soldiers killed in action rose and the war became increasingly unpopular, the draft became a focal point for antiwar protestors. In 1973 President Richard M. Nixon (1913–1994) signed legislation that ended the draft, and those joining the military thereafter did so as volunteers.

THE SELECTIVE SERVICE IN THE EARLY-TWENTY-FIRST CENTURY

Despite the end of the draft, in the early-twenty-first century the Selective Service exists as a contingency in the event of a draft. All males in the United States must register within thirty days of their eighteenth birthdays; that requirement applies to citizens and aliens alike. Registrants may sign up via mail, at a U.S. post office, or on a student federal financial aid form. Because the Selective Service does not apply draft status classification to registrants when there is no draft, disabled men must also register. Similarly men who are conscientious objectors to war must register with the Selective Service, since there is no place on the registration form to indicate objection to induction into the armed services. The mere act of registering, however, does not guarantee a man will be inducted in the event of a draft. As it did during previous wars where a draft was in place, the Selective Service would classify registrants to determine eligibility for induction and deferments when and if a draft is reinstated. Additionally, according to its mission statement, the Selective Service would devise an alternative service program for those classified as conscientious objectors.

Females are not required to register with the Selective Service. Congress has explicitly stated in all Selective Service legislation that only males are required to register. In a 1981 case challenging the constitutionality of that particular clause (Rostker v. Goldberg), the Supreme Court ruled that Congress was well within its authority to exclude women from registration with the Selective Service because the purpose of the legislation is to raise and regulate armies and navies for combat action, and women are excluded from nearly every type of military combat. President William J. Clinton (b. 1946) ordered a review of the policy regarding females and Selective Service registration in 1994, and the Department of Defense reported that the process of exclusion remained justifiable because of combat regulations and restrictions but noted the need to revisit the issue as the roles of female soldiers expand in the future.

In the event Congress passes legislation reinstating the draft, a National Draft Lottery would be conducted to determine the order in which men would be drafted for induction. The lottery would be based upon the birth dates of registrants, beginning with those men twenty years of age during that calendar year. A major difference from the Vietnam draft-era is that registrants who are eighteen and nineteen years old during the year of the draft would most likely not be called, as opposed to the great number of men under the age of twenty called to Vietnam. The lottery would be conducted in public and under the auspices of the National Institute of Standards and Technology in order to insure as random a lottery as possible.

Self Discrepancy Theory

Self discrepancy theory was introduced by psychologist E. Tory Higgins (1987) with the purpose of explaining the relationship between aspects of the self and affect. In this theory, Higgins posits that individuals possess different types of self-guides, or standards, against which they compare their current self. These comparisons yield information that individuals are either near their self-guides or are distant from them. In the case of proximity to self-guides, individuals experience positive affect. In the case of discrepancy from self-guides, individuals experience negative affect. This affect is differentiated by the type of self-guide being used in comparison. Individuals may compare themselves to an ideal self-guide, which represents their hopes or wishes. Or they may compare themselves to an ought self-guide, which represents their obligations or responsibilities. Comparisons made to ideal self-guides result in affect along an elation-dejection spectrum: Proximity to ideal standards yields affect such as happiness and joy, while discrepancy from ideal standards yields affect such as depression and sadness. Comparisons made to ought self-guides result in affect along a relief-agitation spectrum: Proximity to ought self-guides yields affect such as calmness and contentment, while discrepancy from ought self-guides yields affect such as nervousness and guilt. The magnitude of discrepancy is related to the experience of negative affect such that the greater the discrepancy, the greater the negative affect.

Timothy Strauman (1992) applied self discrepancy theory to psychological disorders of emotion. He found that individuals reporting symptoms of depression had larger discrepancies from their ideal selves, while individuals reporting symptoms of anxiety had larger discrepancies from their ought selves.

Self discrepancy assumes that self-regulation occurs in response to the negative affect experienced as the result of a discrepancy. This self-regulation occurs through a discrepancy-reducing feedback process in which individuals exert changes on their behavior in response to a noticed discrepancy. Feedback about individuals’ progress toward self-guides is transmitted back to the individual, and behavioral change is either continued or terminated.

An expansion of this theory by Higgins (1997) suggests that individual differences in self-guides are chronic and related to personality. He labeled individuals who tend to have accessible ideal self-guides as promotion-oriented and individuals who tend to have accessible ought self-guides as prevention-oriented. These different types of goal orientations are expected to influence the types of goals individuals pursue, as well as the contexts under which they will experience the most successful goal pursuit.

Measurement of discrepancies often occurs through the Selves Questionnaire. On this questionnaire, individuals list attributes associated with each of the different self-states (own-actual, own-ideal, own-ought, other-actual, other-ideal, other-ought). Correlations and partial correlations among the self-states are computed to determine magnitude of discrepancy. Some researchers may opt to use only the self-states from the individuals’ own perspective.

SELF-ACTUALIZATION

Self-actualization is the process by which an organism or person realizes its full potential. The concept was first introduced by the Gestalt psychologist Kurt Goldstein in his 1939 book The Organism. It was soon adopted and developed by several early proponents of the humanistic psychology movement, such as Carl Rogers (1902–1987), the founder of client-centered therapy. Nonetheless, self-actualization is most strongly associated with the work of Abraham Maslow (1908–1970), another early humanistic psychologist. It is for that reason that this article will focus on Maslow’s original formulation of self-actualization and subsequent research on that formulation.

HIERARCHY OF MOTIVES

Maslow’s first discussed self-actualization in the context of his argument for a motive hierarchy. This hierarchy was put forward in his article on “A Theory of Human Motivation” published in a 1943 issue of Psychological Review. According to this early formulation, human needs could be ordered according to their relative pre-potency. That is, a particular need will not manifest itself until a more basic, pre-potent need is first satisfied. The most pre-potent motives are physiological and pertain to self-preservation. These include the needs to breathe, to drink water, to eat food, to dispose of bodily wastes, to sleep, and to regulate body temperature. If these needs are reasonably well satisfied, another set of motives are evoked, namely, those that concern safety. This includes the desire for physical security, such as the need to live in a secure, predictable environment free of violence and threat. Once this set of needs is also gratified, the individual advances to love needs, which include the desire for affection, intimacy, and belongingness.

After physiological, safety, and love needs are satisfied, the person can move to esteem needs. These involve the enhancement of one’s self-confidence and self-respect. Only upon the gratification of esteem needs can an individual progress to the need for self-actualization. According to Maslow, this “refers to the desire for self-fulfillment” or “the desire to become more and more what one is, to become everything that one is capable of becoming” (1943, p. 383). Because each individual human being has a distinct intrinsic potential, self-actualization is the most divergent of the needs in the hierarchy. Everyone can appreciate the desire for a breath of fresh air, the need to feel safe from danger, and the push to feel good about one’s self. But where one person might self-actualize by becoming a scientist, another might do so by becoming an athlete or chef. There are as many ways to self-actualize as there are distinguishable individuals. However, because a large number of persons never are able to satisfy more pre-potent needs, self-actualizing individuals tend to be relatively rare.

From 1943 until Maslow’s death in 1970, this formulation underwent several modifications and elaborations. One important change was the later distinction between deficiency and being needs. The former “D-needs” encompass the physiological, safety, love, and esteem needs. To experience these needs is to succumb to “D-cognition,” or the awareness of a deficiency—of a negative condition that must be removed. The latter “B-needs,” in contrast, concern “B-cognition,” or the awareness of pure being—a positive state that is actively enjoyed. In this second group Maslow placed not just self-actualization but also various higher motives, such as the needs for knowledge, for aesthetics and beauty, and for self-transcendence, a spiritual need. Unlike the deficiency needs, Maslow’s conception of the being needs changed over the course of his career. These changes involved both their number and their placement within the hierarchy.

CHARACTERISTICS OF SELF-ACTUALIZERS

Having placed self-actualization at or near the apex of the motive hierarchy, Maslow felt it necessary to investigate the attributes of those personalities whose lives are dominated by B- rather than D-cognition. This presented a methodological problem because, according to his theory, self-actualizing individuals should be relatively rare. In fact, he reported that in student populations—the most common source of research participants in psychological research—only 1 out of 3,000 students managed to get beyond deficiency needs. As a consequence, Maslow adopted an unconventional investigative strategy. Rather than study self-actualizing students he would examine eminent personalities whose acts of self-actualization had driven them to major achievements. His sample included, among others, first lady and humanitarian Eleanor Roosevelt, the African American abolitionist Frederick Douglass, the physicist Albert Einstein, the psychologist and philosopher William James, the German poet Johann Wolfgang von Goethe, the Spanish violoncellist and conductor Pablo Casals, and the French painter Pierre-Auguste Renoir.

For each of the sampled self-actualizers Maslow collected biographical information about their personal characteristics. From that information he abstracted a sketch of the typical self-actualizing personality. In particular, self-actualizers were found to have more accurate perceptions of reality, to be more accepting of themselves and others, to display a freshness of appreciation for the world around them, to be more spontaneous, to be more problem centered rather than self centered, to exhibit a strong need for privacy, to maintain deep personal relationships
with just a few select individuals, to harbor a powerful sense of kinship to fellow human beings as well as a great deal of humility and respect for others, to have strong but somewhat unconventional ethical standards, to concentrate on ends rather than means, to be autonomous and to resist enculturation, to project a more intellectual than aggressive sense of humor, to be more creative, and to undergo special cognitive-emotional moments that Maslow called peak experiences. The latter experiences were especially important as motivators in the self-actualization process.

EMPIRICAL RESEARCH
Because Maslow was reacting against the predominant behaviorism of his day, his research on self-actualization did not meet contemporary standards for scientific rigor. For instance, his motivational hierarchy was not based on a series of laboratory experiments regarding the relative strengths of various human needs. Although he could be said to have collected data for his global profile of the self-actualizing personality, his analyses were qualitative and subjective rather than quantitative and objective. Moreover, his criteria for identifying certain individuals as being self-actualizers appear in retrospect to be somewhat haphazard or idiosyncratic.

Nevertheless, subsequent researchers have tried to scrutinize Maslow’s theory using more conventional methods. Some of this research has focused specifically on the hierarchy of motives. On this point it soon became clear that the empirical data did not lend much if any support to the hypothesized ordering of needs. Not only is the drive priority unstable or variable within the set of D-needs, but also it is the case that B-needs can sometimes take precedence over D-needs. This possibility is suggested by the proverbial image of the “poor starving artist in the attic” who places self-actualization before the supposedly pre-potent needs for food, companionship, and a warm bed. Although Maslow himself acknowledged that the motivational priorities can sometimes be upset in particular cases, he often viewed these departures as pathological rather than healthy. Furthermore, once one allows for individual differences in the hierarchical placement of the motives the whole concept becomes seriously weakened as a scientific explanation. A hierarchy that can assume almost any form across separate personalities can hardly be viewed as a legitimate hierarchy.

A far larger body of empirical research has concentrated on Maslow’s profile of the self-actualizing person. Unlike Maslow’s own work, this research has relied on the development and application of psychometric instruments that directly assess a person’s self-actualization. The first such measure was the Personal Orientation Inventory created by researcher Everett L. Shostrom in 1963. Although this instrument was used extensively throughout the 1970s and 1980s, it was also subjected to numerous criticisms with respect to validity and reliability. In the late 1980s and 1990s alternative measures appeared, including the Jones and Crandall (1986) Short Index of Self-Actualization and the Sumerlin and Bundrick (1996) Brief Index of Self-Actualization. Taken together, research using these instruments has helped validate much of what Maslow had concluded from his eminent creators and leaders. For instance, self-actualizers tend to display superior mental health, to have higher self-esteem, to have lower anxiety, to have more purpose in life, and to be more creative, hopeful, optimistic, and independent. Furthermore, investigations have indicated some of the factors that help increase the level of self-actualization, such as specific meditation practices and therapeutic interventions. Hence, there is little doubt that self-actualization is an observable and significant psychological phenomenon.

CRITICAL EVALUATION
By the twenty-first century self-actualization had acquired a somewhat ambivalent position in the psychological sciences. On the one hand, the concept of self-actualization—including Maslow’s formulation of its placement in a hierarchy of motives—remains extremely well known. The word continues to be used by many applied psychologists, especially those active in clinical, counseling, educational, and industrial psychology. Moreover, numerous introductory textbooks in psychology still include an almost obligatory section on Maslow’s motive hierarchy. On the other hand, empirical research on self-actualization waned considerably after the 1990s. Indeed, an article on the subject has not been published in a top-tier psychology journal since the 1980s. All of these trends may suggest that its utility as a psychological concept has diminished to the point that its status has become more historical than scientific. Even so, it is hard to imagine that the idea will disappear from popular psychological thought. The concept of self-actualization has entered mainstream culture in a manner almost comparable to the ideas of the Austrian neurologist Sigmund Freud, the father of psychoanalysis. Therefore, it is unlikely that the concept will ever completely retreat into the history books. Furthermore, interest in the construct has undergone something of a revival in the mid-2000s with the advent of the positive psychology movement, which concerns itself with the empirical study of human virtues.

SELF-AFFIRMATION THEORY

Sometimes people have thoughts and experiences that threaten their self-image. According to Claude Steele's (1988) self-affirmation theory, when people's self-image has been threatened they are motivated to affirm the integrity of the self. Moreover, people have a desire to restore their general self-image, not simply to resolve the specific threat. The unique prediction that self-affirmation theory makes is that people have a strong desire to maintain a positive self-image; therefore, when people experience a specific self-threat, they can overcome the unpleasant arousal associated with the threat by affirming an equally important, yet unrelated, aspect of the self. This can work to restore self-esteem even without resolving the specific threat.

Self-image threats can arise from several sources. One important source is when people hold inconsistent cognitions or engage in behaviors that are inconsistent with their beliefs. For example, some people fail to practice safe sex on a regular basis, although they are aware of the health risks associated with such actions. Likewise, some people do not drive energy efficient cars, although they profess to have positive attitudes toward environmental issues. When people hold two conflicting cognitions or when they behave in a way that is contrary to how they think they should act, they often experience an unpleasant psychological state that is referred to as cognitive dissonance. The inconsistency between one's cognitions and behavior can be arousing and threatening to the self because it suggests that people are irrational, immoral, and even unintelligent.

According to cognitive dissonance theorists, people often try to reduce this unpleasant psychological state by engaging in one of three actions. First, people may attempt to change their behavior to make it more consistent with their cognition. For example, smokers can stop smoking. Second, people can attempt to reduce cognitive dissonance by changing their cognitions. Smokers, for example, can lower their perception of the health risks associated with smoking. Finally, people can attempt to reduce cognitive dissonance by adding new cognitions to their belief system. For example, smokers can focus on counterexamples to the health risk by focusing on people who smoke but have lived a very long life. Additionally, smokers may justify their behavior by emphasizing how much smoking reduces their stress level. These three basic ways of reducing cognitive dissonance involve changing beliefs and actions within the domain in which the self has been threatened. For example, in order to restore their self-regard, smokers must engage in some affirmation strategy that is directly relevant to smoking behavior. Self-affirmation theory, however, predicts something different. It states that when people experience a self-image threat after engaging in an undesirable behavior in one domain, they can restore their self-image by affirming another aspect of the self. As with the smoking example, smokers can restore their self-image by reminding themselves that they contribute to charities for impoverished children or that they have a lot of friends. In this example, contributing to charities or focusing on being well liked are unrelated to the domain of smoking and yet serve the function of making people feel good about themselves after a threat.

Threatening thoughts and experiences can also arise from the way people are treated or are perceived to be treated by other individuals. The perceptions and behaviors of other individuals can pose a threat to a person's personal self-worth. For example, being accused of being uncooperative may threaten a person's self-esteem because most people desire to appear cooperative. Additionally, other individuals' perceptions and behaviors can pose a threat to a person's collective self-worth. For example, being considered unintelligent because one is black may threaten a person's collective self-esteem or sense of self as a member of a particular group. When people feel threatened because they sense that they are judged or treated in terms of social stereotypes or that they might do something that could inadvertently confirm the stereotype, they experience what Steele (1997) refers to as a stereotype threat. According to self-affirmation theory, when people experience a stereotype threat they can reaffirm the self even in a domain unrelated to the stereotyped domain. For example, an African American student who is stereotyped by his teacher as unintelligent can reaffirm the self by thinking about how great he is at negotiating interpersonal conflict.

Self-affirmation theory suggests that there are many possible ways that people can protect their self esteem when it is under threat. Specific threats may come from inconsistencies in thoughts and behaviors that may lead to
a state of cognitive dissonance or the presence or perceived presence of societal stereotypes of a particular group. Whatever the source, research has found that affirming an aspect of the self that may even be unrelated to the self threat is effective in making people feel good about themselves, at least in the short term.

SELF-AWARENESS THEORY
Self-awareness is the capacity to take oneself as the object of thought—people can think, act, and experience, and they can also think about what they are thinking, doing, and experiencing. In social psychology, the study of self-awareness is traced to Shelley Duval and Robert Wicklund’s (1972) landmark theory of self-awareness. Duval and Wicklund proposed that, at a given moment, people can focus attention on the self or on the external environment. Focusing on the self enables self-evaluation. When self-focused, people compare the self with standards of correctness that specify how the self ought to think, feel, and behave. The process of comparing the self with standards allows people to change their behavior and to experience pride and dissatisfaction with the self. Self-awareness is thus a major mechanism of self-control.

Research since the 1970s has strongly supported self-awareness theory (Duval and Silvia 2001). When people focus attention on the self, they compare the self with standards, try harder to meet standards, and show stronger emotional responses to meeting or failing to meet a standard. The tendency to change the self to match a standard depends on other variables, particularly perceptions of how hard it will be to attain the standard. Remarkably, many experiments have shown that when people are not self-focused, their actions are often unrelated to their personal standards—self-awareness is needed for people to reduce disparities between their actions and their ideals.

Self-awareness theory was enriched by new research methods. According to the theory, anything that makes people focus attention on the self will increase self-awareness. Researchers accomplish this by placing people in front of large mirrors, videotaping them, having people listen to recordings of their voices, or making people feel like they stick out. Momentary levels of self-awareness are measured by people’s use of self-referential words and pronouns and by how quickly people recognize self-relevant information.

Self-awareness theory remains a fruitful and controversial theory. One new direction is the application of self-awareness theory to clinical disorders involving negative self-evaluation (e.g., depression) and excessive self-consciousness (e.g., social anxiety). One controversy, reviewed by Paul Silvia and Guido Gendolla (2001), is whether self-awareness enables accurate judgments of the self. Many researchers have proposed that self-awareness creates clearer perceptions of internal states, emotions, and traits. Other researchers, however, have noted that the self-concept is fluid, complex, and contextual—it is not a static object that can simply be apprehended and examined. Ironically, by making some aspects of the self especially salient, self-awareness may exaggerate and bias judgments of what the self is like.

SELF-CLASSIFICATION
Self-classification occurs anytime an individual reports an identity, characteristic, or membership within a social group. Though the use of self-classification as a discrete form of measurement coincides with the twentieth-century popularization of social surveys in Britain and the United States (Gordon 1973), the origins of classification have roots in antiquity. Efforts to systematically distinguish plants from animals began with Aristotle, and fol-
following the influential work of the Swedish botanist Carolus Linnaeus (1707–1778), classification became the scientific standard for expressing organizational hierarchies in the natural world (Frängsmyr, Lindroth, Eriksson, and Broberg 1983). Taxonomic classification groups individual units by the number of properties they share, with broad, loosely related parent categories subdivided into more detailed, closely related subcategories. Societies are also organized hierarchically, and to the extent that population groups differ on outcomes of interest to social scientists, classification can be viewed as a prerequisite of all comparative research and studies of inequality in particular.

In the natural sciences units are classified by the investigator, and taxonomies are assumed to represent objective groupings based on universal laws. Social taxonomies are embedded within social relations, however, and cannot be viewed as objective or universal (Durkheim [1912] 1965). Subjects often classify themselves in social research, and many surveys, polls, and population censuses are composed entirely of self-reported data.

In many ways self-classification has revolutionized social research, particularly in areas of attitude and opinion polling. Self-reports of personal well-being, self-esteem, and presidential approval are common examples of types of subjective measures widely used in cross-sectional comparisons and trend analyses. Even objective information such as height and weight can be self-classified without incurring the costs of direct measurement.

Because self-reports are inherently subjective, however, they sometimes provide inaccurate or unreliable measures of objective characteristics. People may lack relevant knowledge about their personal histories; even seemingly straightforward measures, such as the place and timing of birth, are unknown in certain instances. In other cases, individuals may misrepresent themselves, particularly on measures that are perceived to be intrusive or potentially stigmatizing, as with measures of income, substance abuse, and even height or weight (Strauss 1999). Although advances in questionnaire design and interview techniques have improved the quality of self-reported data, there are limits to what these advances may achieve. For example, many individuals are unwilling to self-classify as perpetrators of discrimination on survey questionnaires, which has spurred the development of “deception designs,” such as housing and job search audits, that can be used to circumvent respondents’ reluctance to admit socially undesirable behavior (Yinger 1986).

Discrepancies between self-classification and direct measures are also a risk when the constructs underlying those measures reflect a combination of objective and subjective realities. Many axes of inequality fit this criterion. Though concepts such as race, class, and gender can be reduced to ostensibly objective terms (ancestry, income, and sex, respectively), these simplifications ignore the social embeddedness of identity, which is shaped by the dynamic interplay between social actors, institutional forces, and historical contingencies. Systems of racial hierarchy evolved quite differently in North and South America (Graham 1990), for example, so it is plausible for similar-looking individuals from each region to self-classify in different ways. Because identities reflect the social construction of race in each region, however, it is inappropriate to view one identity as more accurate than the other, much less to justify the use of “objective” criteria, such as ancestral descent, which may have little bearing on the social consequences of race in these regions.

SELF-CONCEPT

The self has a long history of study within the psychological tradition, dating back to early work by William James in his seminal book The Principles of Psychology (1890). Throughout the next century of study, self-concept was examined by numerous researchers who emphasized both internal characteristics and external influences on the self-
concept. Though some researchers have looked at self-concept as a global construct, many agree that the self-concept is composed of multiple components. Much of the research has focused on the cognitive structure of the self-concept as well as the related evaluative component of self-esteem. In general, the self-concept is an individual’s perceptions of the self arising from multiple components, including how one sees oneself in interaction with others as well as how one views oneself in isolation.

DEVELOPMENT
Susan Harter wrote extensively about self-concept development in her book The Construction of Self: A Developmental Perspective (1999). Her detailed account of the emergence of self-concept begins as the self-concept appears around the age of two, first manifesting as a recognition of the self as a distinct physical entity. The development of autobiographical memory is important in the emergence of self-concept in that before the age of two, children may have generic memories but do not yet have a memory of the self. Through discourse with parents in which past events involving the child are recounted, children begin to form autobiographical memories and an evolving autobiographical portrait of the self. Another important influence on the emerging self-concept of children is the attachment relationship with the caregiver. From the attachment relationship, children form internalized representations of others and how the self fits into the social world. This is important to the child’s asserting his or her unique influences on the world and to viewing the self as a unique entity interacting with the external world.

Increasing cognitive and social demands cause the development of the child’s self-concept to change from being based upon only a few components or poorly clarified to a more organized and clear formulation based on several clearly distinct domains. Different roles that are required of children as development progresses require the child to develop different sets of behaviors and personality characteristics according to the current role. Some of these roles and traits may clash, such as when a child sees him- or herself as warm and friendly with peers and moody and unresponsive with parents. As the child moves into adolescence, cognitive capabilities enable the child to integrate all of these roles and clashing components into a coherent sense of self.

SELF-WORTH AND SELF-ESTEEM
Another important component of Harter’s account of the development of self-concept is the idea of self-worth. Self-worth is determined from the evaluation of the components of the self; Harter stresses that self-worth is formed primarily from areas that are important to the self. This echoes the ideas of William James and asserts that not only is the self formed of multiple components, but also that these components differ in their importance to the individual. Each component is evaluated separately, such that individuals may feel they are skilled in some domains and not as skilled in other areas. Harter contends that these areas of importance are developed through feelings of competence in different areas. In an individual with a positive sense of self, the areas in which he or she feels competent are more highly weighted than those areas in which he or she does not feel competent.

This close connection between self-concept and self-worth suggests that self-concept is closely related to its evaluative side, frequently termed self-esteem. Though often talked about as separate constructs, these two areas may be difficult to separate, as Harter points out that many of the components of the self are evaluative in nature. For example, when asked to define the self-concept, an individual might list adjectives such as “smart,” “funny,” or “good-looking.” However, these words are in themselves evaluative. Thus the self-concept and self-esteem are two constructs that are discussed as though they are separate, but in fact they are closely related.

STRUCTURE
Another area subject of study closely related to the self-concept is the cognitive structure of the self. Social cognition researchers view the self-concept as an organized set of knowledge about the self, and as such, how the different components are organized becomes important. Herbert Marsh and Richard Shavelson developed an influential theory of the self as organized in a hierarchical structure (1985): A stable sense of self is at the apex of the hierarchy, which then branches into academic and nonacademic components, and each of these further differentiates into more specific self areas.

Patricia Linville made important contributions to the literature on the self-concept structure with her self-complexity theory (1985), which asserts that the knowledge about the self is organized into multiple cognitive structures known as “self-aspects.” These self-aspects are organized in relation to each other, with related aspects being linked in a network structure. Different social contexts and cognitions activate different self-aspects, which in turn activate other linked aspects. The complexity of the self-concept is a result of both the number of self-aspects and the interrelatedness of those aspects. A complex self-concept is composed of a large number of independent aspects.

Linville further asserted that having a complex self-representation is positive for mental health. This is due to the network structure of the self. When a negative event occurs in an area related to one self-aspect, the individual is likely to experience negative affect in that area. A sim-
ple self structure may have two important consequences. First, if there are few self-aspects, the negatively affected area represents a large part of the self, and so a negative event leads to negative feelings about the self. Second, if the self-concept is composed of highly interrelated aspects, then this negative event is likely to trigger negative feelings in all other associated areas; Linville referred to this as affective spillover. In these two ways a simple self-concept is more affected by any one event, whereas a more complex self-concept has more stability. According to Linville, a complex self-concept leads to more stability in affect, which is associated with better mental health. Later studies have questioned these ideas and aimed to clarify the effects on self-complexity on mental health.

One example of this is Carolyn Showers’s 1992 investigation of how positive and negative self-aspects may be separated or related. Showers found that how they are related matters to levels of self-esteem and depression. When positive self-aspects are important to overall self-worth, compartmentalization of positive and negative aspects results in higher self-esteem and reduced levels of depression. In contrast, when negative self-aspects are important, compartmentalization is associated with negative effects, and furthermore, when negative self-aspects are important, a more complex self is better for positive psychological well-being. Therefore, one modification to Linville’s 1985 theory has been that the content of the structure matters to the buffering impact as well as to the structure. Other clarifications have also been made to more fully understand the impact of self structure.

Some theorists have argued that the content and structure of the self-concept are unrelated, whereas others, such as Showers, argue that they work in concert. Although there is a distinction between what can be defined as content and structure in the self-concept, several studies suggest that both of these areas are important.

FLEXIBILITY

Another topic in the self-concept literature is the debate about whether the self-concept is dynamic or stable. Some scholars argue that the self-concept is stable once formed; others maintain that it is a more malleable construct. Some social cognition researchers view the self-concept as both stable and changing: There are components to the self that are stable across situations, but there are also components that may change in their expression depending on the context. For example, when asked about his self-concept, a young man in school might mention intelligence as an important part of himself, but in a social setting he might stress social skill as more important. Context as well as self-presentation issues may come into play as important in terms of viewing the self as stable or malleable.

MEASUREMENT ISSUES

With such a broad field of study, there are many ways to measure self-concept. Explicit measures of self-concept are often used to assess different areas that an individual might find important to the self. Examples of commonly used explicit measures include the Piers-Harris “Children’s Self-Concept Scale” (1969), Susan Harter’s “Self-Perception Profile” (1985), and Marsh and colleagues’ “Self-Description Questionnaire” (1984). Implicit measures of self-concept and self-esteem are also used; one example is the “Implicit Association Test.” This measure examines response times between sets of stimuli and is based on the idea that items that are cognitively related should have a faster association than items that are unrelated (Greenwald, McGhee, and Schwartz 1998).

SELF-CONSCIOUSNESS, PRIVATE VS. PUBLIC

Many organisms exhibit at least a rudimentary form of self-awareness by which they experience themselves as dis-
tinct from their environment. However, humans are capable of more profound and consequential forms of self-awareness that make possible uniquely human capacities such as introspection and self-reflection. Although all normal-functioning people are sometimes self-aware, some people are consistently aware of themselves. The tendency to consistently direct attention toward the self is referred to as self-consciousness.

According to Arnold Buss, to whom the seminal research on self-consciousness is attributed, the tendency to consistently direct attention toward the self is evidenced in the highly self-conscious person in the following ways:

- An intense focus on behavior—past, present, and future
- A heightened sensitivity to privately experienced feelings
- Recognition of positive and negative characteristics in oneself
- A tendency to introspect
- Imagining oneself
- An awareness of how one appears to others
- Concerns about others’ appraisals

A distinction typically is drawn between forms of self-consciousness corresponding to the two distinct vantage points from which people can direct attention toward themselves and the different aspects of the self experienced from those vantage points. Private self-consciousness is the tendency to focus on oneself from a personal vantage point and attend to aspects of the self that are not readily apparent to others, such as one’s thoughts and feelings. Public self-consciousness is the tendency to focus on oneself from the perceived vantage point of real or imagined others and to attend to aspects of the self that are observable by others, such as facets of one’s appearance and behavior.

The origins of the contemporary empirical literature on self-consciousness can be traced to the 1975 publication of the Self-Consciousness Scale by Allan Fenigstein, Michael F. Scheier, and Arnold H. Buss. Although the measure includes a set of items that reflect social anxiety, the primary use of the measure is for the item sets corresponding to the two major forms of self-consciousness. These items are used in virtually all empirical research on individual differences in the tendency to direct attention toward the self. Respondents indicate the extent of their agreement or disagreement with statements such as “I’m generally attentive to my inner feelings” (private) and “I’m usually aware of my appearance” (public). Composite scores on these item sets serve to index private and public self-consciousness. These scores are modestly correlated, suggesting that the tendency to focus on oneself from one vantage point is not necessarily accompanied by a tendency to focus on oneself from the other vantage point.

Psychometric analyses of the Self-Consciousness Scale have routinely identified a schism in the set of private self-consciousness items. Not only do the items reliably cluster in two sets, but scores on these item sets are not strongly related to each other and are differentially related to other variables. Internal state awareness is a rudimentary, non-evaluative form of private self-consciousness, typified by the statement, “I reflect about myself a lot.” Scores on internal state awareness are positively correlated with variables that indicate psychological health. Self-reflectiveness is an evaluative form of private self-consciousness, typified by the statement, “I’m constantly examining my motives.” Scores on self-reflectiveness are positively correlated with a set of variables that, on the whole, indicate poor psychological health. In comprehensive models of self-awareness, internal state awareness is an instance of objective self-awareness, not unlike the rudimentary forms of self-awareness experienced by nonhuman species. Self-reflectiveness is an instance of symbolic self-awareness, the uniquely human form of self-awareness that makes self-evaluation possible and inevitable.

Research in which these forms of self-consciousness as measured by the Self-Consciousness Scale are studied in relation to other variables does not allow for an evaluation of the extent to which self-consciousness is a causal factor. That evaluation requires experimental research, which involves randomly assigning people to manipulated levels of self-consciousness. Indeed, it is now evident that laboratory manipulations of self-consciousness produce relations with other variables that mirror the relations evidenced when self-consciousness is measured using the Self-Consciousness Scale. Private self-consciousness has been manipulated in several ways. The most frequently used method involves exposing people to an image of their face in a small mirror. Other manipulations include having people listen to their own voice or their own heartbeat; instructing people to focus on themselves; and having people write a story in which they are the main character. Public self-consciousness has received less attention in experimental research but has been successfully manipulated by exposing people to an image of their body in a full-length mirror or having people watch themselves on video. Using these manipulations, people who have been induced to focus attention on themselves can be compared to people who have not been so induced on outcome variables of interest to evaluate the potential causal influence of self-consciousness on those variables.

Findings from research using the Self-Consciousness Scale and laboratory experiments in which self-consciou-
Self-consciousness is manipulated indicate that self-consciousness is implicated in a host of social attitudes, emotions, and behaviors. Private self-consciousness is associated with better access to self-knowledge, and a greater interest in new self-knowledge regardless of whether that knowledge is positive. As a result, the self-knowledge of people high in private self-consciousness is associated with a more prominent role in their behavior. For instance, compared to people low in private self-consciousness, their attitudes are more predictive of their behavior; they are less likely to conform when their opinions are challenged; and they are more resistant to inaccurate suggestions about their own sensations. Private self-consciousness also is associated with emotional experience. Because introspection often leads to self-criticism, private self-consciousness can give rise to negative emotion. In addition, attention directed toward private self-aspects appears to intensify current emotional experience—positive or negative.

Public self-consciousness is associated with phenomena that involve perceptions of how other people view the self. For instance, public self-consciousness is associated with a greater concern for appearance as evidenced by wearing more makeup and showing greater concern about balding. Compared to people low in public self-consciousness, people high in public self-consciousness are more likely to conform to group pressure; they are more accurate in their perceptions of how others perceive them; and they are more likely to experience aversive social emotions such as shyness and social anxiety.

Self-consciousness in its two forms—private and public—is a fundamental human trait relevant to a broad range of attitudes, emotions, and behaviors of interest to social scientists. Because humans experience forms of self-consciousness that no other organism experiences, the study of self-consciousness addresses the fundamental question of what it means to be human.

SELF-CONTROL

Self-control has been defined as the capacity that individuals have to exert control over their own thoughts, emotions, impulses, and performance. A central component of this definition is that self-control involves overriding or inhibiting something that would otherwise occur. A wide variety of concepts related to self-control have been studied in the field of psychology. These include self-regulation, willpower, and delay of gratification.

Many scholars have used the terms self-control and self-regulation interchangeably. Self-regulation can be defined as the self-governing process by which individuals monitor, evaluate, and modify their behavior in regard to standards. In this process behavior is evaluated in terms of standards or reference values. After the evaluation phase, an operation phase ensues. During this phase, individuals’ current behavior is compared to a desired or undesired end state. If a discrepancy is noticed between one’s self and standard, the results are negative and imply that individuals should change their behavior in a way that brings them more in line with their standards. If no discrepancy is noticed, the results are positive and imply that individuals should maintain their present course of behavior. The process of exerting self-control is often thought to parallel that of self-regulation. Exerting self-control is probably best viewed as a particular case of self-regulation in which overriding or suppression of an undesired response occurs. Hence any event that requires self-control occurs in the larger framework of self-regulation. However, it is not the case that any event that involves self-regulation could be described as requiring self-control.

The predominant view of self-control has been as a personality characteristic. This trait is influenced by temperament, parental factors such as socialization, attachment, and warmth, and demographic factors such as neighborhood safety and family socioeconomic status. In adults personality characteristics related to self-control include impulsivity, sensation seeking, conscientiousness, and emotional stability. Impulsivity and sensation seeking are negatively correlated with self-control, whereas conscientiousness and emotional stability are positively correlated with self-control.

SELF-CONTROL AND BEHAVIOR

As a trait, self-control is connected with a wide variety of behaviors and problems. In their 2004 work the
researchers June Tangney, Roy Baumeister, and Angie Boone showed convincingly that high levels of self-control are associated with better adjustment whereas low levels of self-control are associated with poorer adjustment and interpersonal problems. In their research high self-control was associated with lower levels of alcoholism, higher grade point averages, less eating disorder symptomatology, and less aggression. Other research has shown that poor self-control skills are related to problems with weight control and overeating, alcohol misuse and drug addiction, impulsive consumer purchasing and behavior, and crime and delinquency. In fact self-control is a central component of the general theory of crime proposed in 1990 by Michael Gottfredson and Travis Hirschi. In this theory self-control is related to crime because individuals with varying levels of self-control consider the consequences of their behavior to different extents. Individuals with high self-control consider the long-term consequences of their behavior, while individuals with low self-control do not.

A different line of research on self-control has focused on the differences between attending to short-term and long-term benefits of behavior. Delay of gratification is a particular type of impulse control in which individuals opt to wait for more preferred rewards in lieu of taking a less preferred reward immediately. In 1988 Walter Mischel showed that the ability to delay gratification is one that increases with age. Additionally his research on delay of gratification supports viewing self-control as a personality variable. In one 1990 study Mischel and his colleagues Yuichi Shoda and Phillip Peake showed that children who waited for longer periods of time to earn rewards became adolescents with better overall adjustment and had higher SAT scores. David Funder, Jeanne Block, and Jack Block provided evidence in the 1980s that the ability to delay gratification is related to a variety of positive outcomes. Children who were better at delaying gratification tended to be calmer, less irritable, less easily frustrated, and less aggressive. They were also better at concentrating and received higher grades than children who were lower in self-control.

Models of self-control vary in the extent to which they view self-control as a skill, as knowledge, or as strength. The largest body of support exists for viewing self-control through a strength model, where self-control is compared to a muscle. In this model individuals have limited regulatory resources or resources available to exert self-control. Individuals who exert self-control suffer a cost in that they may be less able to exert self-control on a subsequent task. In their 1998 work Mark Muraven, Diane Tice, and Roy Baumeister showed that when individuals exert self-control, their regulatory resources become depleted and individuals’ performance on simultaneous activities requiring self-control is impaired. Furthermore exerting self-control on an activity impairs performance on consecutive tasks. This resource for self-control is used for tasks related to regulating affect, behavior, and cognition. Activities that require an individual to exert self-control in one domain can lead to deficits in performance in another domain. For example, individuals who are asked to regulate their emotions by refraining from feeling or expressing them while they watch a sad film clip persist for a shorter period of time at a physical task than individuals who watch the same sad film clip without regulating their emotions. Other tasks that deplete individuals’ resources to exert self-control include making personally relevant and important choices, ostracizing liked others, refraining from temptations, and overriding habits. Individuals can practice exerting self-control and strengthen this “muscle” so that at later times engaging in the practiced activity does not lead to as much resource depletion.

Although the traditional view of self-control is a response to an unwanted event, individuals may exert self-control by avoiding situations that may contain temptations or distractions. This type of self-control is referred to as counteractive self-control. In 1997 Peter Gollwitzer and Veronika Brandstatter provided evidence that implementation intentions can increase the success of goal pursuit, even in the face of obstacles or temptations. An implementation can best be construed in terms of a “when, then” statement. An example might be “when my alarm clock goes off in the morning, then I will get out of bed to exercise.” These intentions connect the desired behavior with the context in which that behavior is expected to occur.

The economist Thomas Schelling defined a similar construct of precommitment. Individuals may exert self-control in this way by planning activities that will preclude, or limit, their potential behaviors. A classic example of this would be a general who commands the army to burn the bridges after it crosses them, thereby limiting the army’s likelihood of retreat. The relationship between intentions, planning, and behavior has sparked other research in self-control. Specifically Judy Fitch and Elizabeth Ravlin studied willpower as it relates to the role of the self in motivation and goal pursuit. Their 2005 work approaches willpower as a subfactor of the personality trait of conscientiousness. Willpower is defined as persistence and determination, or the ability to exert extra effort to attain a desired goal. In their research Fitch and Ravlin found that willpower moderated the relationship between intention and behavior. In other words, individuals who have stronger willpower are more likely to engage in behaviors that reflect their intentions.

Temptations may not always act as obstacles to successful self-control. In 2003 Ayelet Fishbach, Ronald Friedman, and Arie Kruglanski found that the presence of
tampetions is automatically associated with relevant goal pursuit. Individuals who were primed with temptations that might distract them from their goal were more likely to engage in choices and activities related to that goal. When individuals perceived the goal they were pursuing to be important, they were even more likely to associate temptations with goal pursuit. It should be noted that the priming manipulation in this study occurred at a nonconscious level. That is, temptations were not actually present when the goal pursuit of individuals was being assessed. In regard to self-control, this research implies that thinking about temptations ahead of time may increase an individual’s ability to resist them when they are physically present.

In summary, understanding self-control requires viewing it as a function of both the person and the environment. Like many psychological phenomena, both individual and situational factors influence the ways that self-control occurs. Researchers know that individuals vary across personality factors and in their ability to exert self-control and that these differences are attached to meaningful outcomes. They also know that contextual factors such as the presence of temptations lead to fluctuations in how individuals control their thoughts, emotions, and behaviors. Indeed individuals can even influence their own later ability to exert self-control through detailed planning.

**SELF-DEFEATING BEHAVIOR**

A self-defeating behavior is any behavior leading to a lower reward/cost ratio than is available through an alternative behavior or behaviors. Self-defeating behaviors include choosing to suffer, self-handicapping, failure to achieve potential, fear of success, learned helplessness, and procrastination. Such behaviors are learned in a variety of ways but usually are initially adaptive in preventing greater suffering or in obtaining rewards in the situations in which they are originally learned. For example, parents may be less punitive if children are self-critical after doing something the parents do not like than if children do not derogate and punish themselves. Self-defeating behaviors often occur as a consequence of situations that are uncontrollable. For example, if children are punished even when they believe they have behaved well, or if they are rewarded even when they have behaved poorly, they may gain the sense that their behavior does not matter. Then “learned helplessness” is said to occur because the child does not feel as if he or she is in control of what is happening.

Self-handicapping can occur when people receive positive information that they feel may be unwarranted. In order to protect a possible positive view of themselves, people may engage in some sort of excuse making in advance in order to protect a positive, but precarious, self-view or self-esteem. Self-handicapping involves engaging in a behavior known to hurt performance, such as getting too little sleep, using a harmful substance, not studying, or not working hard. A person may choose a task so easy that success is meaningless or so difficult that success is unlikely. Success and failure in such situations do not provide information about one’s comparative ability. Persistence can become counterproductive when it prevents people from engaging in more valuable experiences or when it leads people to exhaust their resources in futile endeavors.

Roy Baumeister and Steven Scher (1988) identified three potential types of self-defeating behaviors: (1) primary self-destructiveness; (2) tradeoffs; and (3) counterproductive strategies. They found no evidence for primary or deliberate self-destructiveness among normal individuals. Tradeoffs occur when people act to gain short-term benefits despite long-term costs—behaviors especially
likely to occur when people are emotionally aroused or highly self-aware. For example, shy people may avoid social situations out of a fear of making a bad impression. Their avoidance of people may lead to greater social exclusion in the future, leading them to be even less confident. They trade the possibility of intimacy to avoid short-term rejection. Or, the cost of medical treatment may lead people to fail to continue it when they do not or no longer perceive symptom relief. Failure to comply may exacerbate their condition in the long run. Counterproductive strategies involve misjudging one's capabilities or the realities of the situation. An example is "choosing under pressure." In this scenario, one may carefully monitor performance in order to do one's best, but the monitoring itself may lead to more anxiety and a poorer performance.

Self-defeating behaviors often simply reflect expectancy-confirmation processes. If we think that we are not good at a particular task, we do not try our best and then perform more poorly than if we had expected that we could excel. People often internalize the expectations held for their gender, race, or social class or by significant others and then engage in self-fulfilling prophecies. If such expectations are negative, then they are self-defeating. A frequent cause of self-defeating behaviors is a desire to maximize self-esteem. There are no consistent effects for high self-reported self-esteem, however. Overconfidence and lack of confidence can both lead to problems.

Sometimes people appear to "choose to suffer" in an effort to (magically) improve their situation in other situations. Such behavior may stem from an unrealistic extension of the work ethic. Research has shown that people expecting an unpleasant event are more likely to choose to engage in another unpleasant activity during the waiting period if they change their beliefs about themselves, such as thinking that they are brave or that they deserve to suffer. If they change their beliefs about the situation, such as thinking it will not be so bad after all, they are less likely to engage in an unpleasant activity during the waiting period.

CLINICAL DISORDERS AND TREATMENT
All clinical disorders could be considered as forms of self-defeating behaviors. A "self-defeating personality disorder" was considered briefly by the American Psychiatric Association, drawn largely from characteristics that had been noted by clinicians since Sigmund Freud (1856–1939) as masochistic. The criteria for the proposed self-defeating personality disorder, however, overlapped too much with those for dysthymic disorder (depression) and other personality disorders, such as dependent personality. Furthermore, feminists were concerned that women who were abused might get labeled as having a personality disorder that brought on abuse, thus leading victims of abuse to be blamed.

All forms of psychotherapy are designed to treat some form of what might be called self-defeating behavior. When people are frightened of situations, behavioral treatments are often the most effective. When people are not clear as to what the problem entails, a treatment involving talking and ascertaining feelings that are necessarily conscious may be appropriate. For example, psychoanalysis has been oriented especially toward understanding if fears of hurting parents or other loved ones interfere with achieving personal goals, such as leaving loved ones all alone, being more successful than they are, or not fulfilling loved ones’ desires to impress other people. Lack of motivation, anxiety, mood disorders, and unrealistic thinking are also treated with medication in combination with psychotherapy.

SELF-DETERMINATION
Self-determination, in the most general sense, refers to the capacity to control one’s own destiny, free of interference by others. Historically, the right to self-determination has meant the right of a subjugated nation or colonized population to establish a sovereign, independent state—to secede from a multinational state or to dissolve colonial ties of dependency to an imperial “mother country.” It has also been invoked in support of demands for local autonomy or self-government at the sub-state level as a means to preserve the culture or safeguard the security of national or aboriginal minorities. Since the 1960s, however, many social movement activists (particularly proponents of a postmodernist “politics of identity”) have sought to invest the principle with a much looser meaning.

NATIONAL SELF-DETERMINATION
The concept of national self-determination is a modern one, despite the fact that struggles by subjugated peoples...
against occupation, colonialism, and enslavement have occurred for many thousands of years. Its advent was predicated on the prior emergence of such defining features of capitalist modernity as the discourse on rights, the ideology of nationalism, and the European nation-state system.

A nation-state is a form of state power in which territorial sovereignty is ostensibly exercised on behalf of a specific nation—a relatively homogeneous aggregation of people who typically share a common language, economic life, and cultural tradition as an “imagined community” (to use Benedict Anderson’s expression). The nation-building projects of modern European states were undertaken to strengthen their positions relative to major rivals and often involved attempts to unify and homogenize the population within the borders of the nation-state, usually through coerced assimilation or “ethnic cleansing” (including forced population transfers and genocide in some circumstances). For several of the major European powers, it also involved the conquest and colonial subjugation of other, far-flung territories and peoples with the aim of consolidating empires whose purpose was to enrich and empower the imperial nation-state or “mother country.” Political domination, military subjugation, and economic exploitation of colonies stimulated the emergence of anti-imperialist movements and nationalist projects within colonized populations otherwise divided along tribal, religious, and linguistic lines.

Independence struggles by the colonial possessions of the major imperial powers began long before the term self-determination came into use. The first such struggle was waged against Britain by several of its “settler colonies” in North America, and its success resulted in the founding of the United States of America in 1776. Encouraged by revolutionary events in France, the black population of Haiti rose up against French rule in the 1790s, eventually establishing an independent republic in 1804. By the late nineteenth century, Spain had lost most of its colonial possessions in the Americas. The success of these New World independence struggles heightened the nationalist aspirations of subjugated nationalities in the multinational states—the Austro-Hungarian, Ottoman, and Russian empires—that dominated much of Eurasia and the Middle East prior to World War I.

Within the imperial nations themselves, few supported the right to self-determination of national minorities at home or colonized peoples abroad. The major exception before 1914 was the international socialist movement. Thus, Karl Marx argued that English wage workers could never achieve their emancipation as a class so long as they remained complicit in the national oppression of the Irish. At its 1896 congress, the Marxist Second International adopted a resolution affirming the right of all nations to self-determination.

In Russia, Vladimir Lenin saw the aspirations of the oppressed nationalities of what he called the czarist “prison house of peoples” as integral to the broader struggle for democracy, insisting that the only way to forge working-class unity across national lines was to combat “great Russian chauvinism” and recognize the right of Ukrainians, Georgians, and other nationalities to establish their own independent states. However, Lenin distinguished between recognizing the right to self-determination and actually advocating independence. The right to self-determination, he wrote, is similar to the right to divorce; one can affirm the right without advising the action. After the victory of the Bolshevik Revolution in 1917, Lenin established the right of nations to self-determination as a fundamental programmatic plank of the Third (Communist) International, advocating national liberation struggles in the colonial world and waging an unsuccessful, deathbed struggle against the Russian chauvinist policies of Joseph Stalin and his acolytes in 1923. The subsequent consolidation of bureaucratic rule under Stalin transformed the Soviet Union into a Russian-dominated multinational state in which the right of the constituent, nationally based republics to secede was extinguished.

At the end of World War I, the principle of national self-determination found a new ostensible champion in the American president Woodrow Wilson, acquiring currency, for the first time, in liberal political discourse. “Self-determination” is not a mere phrase,” Wilson declared in 1918, “it is an imperative principle of action which statesmen will henceforth ignore at their peril” (Moynihan 1994, pp.78-79). But Wilson soon qualified his support for the idea, recognizing the dangers that the principle could pose to European stability. Subsequently, U.S. advocacy of the right of national self-determination proved inconsistent. After World War II, the United Nations, under American leadership, upheld a principle of international law that affirmed the right of colonies to independence from overseas empires but that recognized no right of secession for national minorities within established states.

In the post–World War II era, formal political independence was achieved by the great majority of former colonies in Africa, Asia, and the Western Hemisphere, opening the way, in most cases, to their neocolonial economic and political subjugation by the great powers. However, the demand for self-determination continued to be vigorously asserted by Northern Irish Republicans and Scots in the United Kingdom, Québécois in Canada, Basques in Spain, Tamils in Sri Lanka, and by many would-be nationalist movements operating within the hundreds and perhaps thousands of “imagined communities” that had defined themselves as nations. Under the watchword of self-determination, the 1990s saw the rapid
breakup of the Soviet Union and the Yugoslav federation and the emergence of a plethora of new nation-states in Europe and Asia.

The dispossessed status of the Palestinian people, resulting from the creation of the state of Israel in 1948 and the consolidation of a Hebrew-speaking nation on territory claimed by both Jews and Palestinians as a homeland, remains an intractable national problem at the beginning of the twenty-first century. Here the question arises: Under what conditions can two “interpenetrated peoples” reconcile their mutually conflicting claims to self-determination?

SELF-DETERMINATION AND THE POLITICS OF IDENTITY

The radical ferment of the 1960s inspired a much looser definition of the concept of self-determination, such that it was often used to describe the aspirations of any group confronting putatively oppressive treatment. The original impetus to this redefinition was provided by the 1960s Black Power movement in the United States. Reacting against the liberal, integrationist perspective of the mainstream Civil Rights movement, many African American activists (notably Malcolm X, Stokely Carmichael, and the Black Panthers) embraced black nationalism. Having defined African Americans as an “oppressed nation” or as an “internal colony” (however problematically), these activists proclaimed the right of the black population to various forms of “self-determination”—sometimes through proposals for “separation” from “White America” but more commonly through demands for “black control of the black community.” It is notable that few of these schemes were implemented—their most enduring legacy probably being black studies programs in higher education.

The stage was thus set for the emergence of a decidedly amorphous notion of self-determination, one with which other marginalized or oppressed sectors could easily identify. The concept was also extended to notions of “empowering” individual victims of abuse or poverty through community organizing. Self-determination merged with the broader notion of “liberation” and was invoked by activists who championed not only the rights but also the unique identities of racial and ethnic minorities, women, gays, and the disabled. Indeed, for many advocates of a postmodern “politics of identity,” self-determination became virtually synonymous with unfettered expression of sectoral identity based not only on nationality but on gender, race, or sexual orientation as well.

SELF-DETERMINATION THEORY

Self-determination theory (SDT) is a macro-theory of human motivation, personality development, and well-being. The theory focuses especially on volitional or self-determined behavior and the conditions that promote it, as well as a set of basic and universal psychological needs, namely those for autonomy, competence, and relatedness, the fulfillment of which is considered essential to vital, healthy human functioning.

SDT begins with the assumption that people are active organisms, with inherent tendencies toward psychological growth and development. This active nature is manifest in the phenomenon of intrinsic motivation, the innate tendency to seek out novelty, challenges, and opportunities to learn. It is also evident in the phenomenon of internalization, or the tendency of persons to adopt, and attempt to integrate, ambient social mores and values.

Although the growth tendencies underlying intrinsic motivation and internalization are “natural,” this does not mean that they operate automatically. Instead, these propensities require nutriments from the social environment. These are specified using the concept of basic psychological needs, defined as those supports that are essential and necessary for psychological health. Within SDT there are but three basic psychological needs: autonomy, relatedness, and competence. When these needs are supported and satisfied within a social context, people experience more vitality and self-motivation, as well as enhanced well-being. Conversely, the neglect or thwarting of basic
Self-Disclosure

needs is implicated in most forms of psychopathology and maladjustment (Ryan, Deci, Grolnick, and LaGuardia 2006).

SDT has evolved as a set of four mini-theories. Each mini-theory was developed to explain a set of motivationally based phenomena that emerged from laboratory and field research.

Cognitive evaluation theory (CET) addresses the effects of social contexts on intrinsic motivation. It stresses the importance of autonomy and competence, and it specifically addresses how factors such as rewards, deadlines, feedback, and pressure affect feelings of autonomy and competence and thus enhance or undermine intrinsic motivation.

Organismic integration theory (OIT) addresses the process of internalization of extrinsic motivation. Here the focus is on the continuum of internalization, extending from external regulation to introjection, identification, and integration. These forms of regulation, which can be simultaneously operative, differ in their relative autonomy, and the more autonomous the overall motivation, the greater the person’s persistence, performance, and well-being. OIT further suggests that internalization and integration is facilitated by contextual supports for autonomy, competence, and relatedness.

Causality orientations theory (COT) describes individual differences in how people orient to different aspects of the environment in regulating behavior. When autonomy-oriented, people orient to what interests them and act with congruence; when control-oriented, people primarily regulate behavior by orienting to social controls and reward contingencies; and when impersonally oriented, people focus on their lack of personal control or competence.

Finally, basic psychological needs theory (BPNT) elaborates the concept of basic needs. BPNT posits that each need exerts independent effects on wellness and, moreover, that the impact of any behavior or event on well-being is largely a function of its relations with need satisfaction. Based on BPNT, for example, research has shown that materialism and other extrinsic goals such as fame or image do not enhance well-being, even when one is successful at attaining them. By contrast, goals such as personal growth or giving to one’s community are conducive to need satisfaction, and thus facilitate health and wellness.

Together these four mini-theories constitute SDT. Given its scope, SDT has also spawned active research in numerous areas. One controversial issue has been the impact of rewards, which CET argues can powerfully control behavior, but often at the cost of intrinsic motivation. Another controversy is the cross-cultural generalizability of SDT. SDT suggests that whether collectivist or individualist, Eastern or Western, people function most effectively and experience greater mental health when their behavior is autonomously regulated. Still another issue has been the characterization of well-being. Richard Ryan and Edward Deci (2001) maintained that wellness is not well captured by hedonic measures of “happiness.” Instead, SDT employs the concept of eudaimonia, or wellness defined as the vital, full functioning, as a complementary approach. Finally, because autonomy is facilitated by reflective awareness, SDT stresses the role of mindfulness (Brown and Ryan 2003) in self-regulation and wellness.

The practical implications of SDT in healthcare, education, work, parenting, psychotherapy, religion, and sport contexts are manifold, and the theory has catalyzed considerable applied research and numerous interventions (see Ryan, Deci, Grolnick, and LaGuardia 2006; Deci and Ryan 2000).

SELF-DISCLOSURE

Revealing private personal information to other people is a fundamental characteristic of interpersonal communication. A great deal of research in the social sciences has examined the factors that affect such self-disclosure. Sidney Jourard’s 1964 book The Transparent Self energized self-disclosure research, particularly in the fields of social psychology, clinical and counseling psychology, and communications. Jourard defined self-disclosure as the extent
to which people made themselves “transparent” (or clear) about their inner thoughts and feelings in their self-related communications with others. Jourard’s popular Self-Disclosure Questionnaire contains a broad range of topics including a person’s attitudes and values, tastes and interests, personality, body, and sexuality. On this and similar measures, respondents typically indicate how much they would tell a target person about each topic.

Research suggests that self-disclosure is a fundamental way that relationship bonds are established, developed, and maintained. For example, self-disclosure helps relationship partners to clarify their own actions and intentions and to understand those of their partners. Self-disclosure also helps to increase feelings of intimacy, acceptance, trust, and self-worth within a relationship. For instance, research shows that more intimate self-disclosures are associated with greater liking, and that having disclosed to others increases people’s liking of those persons.

Much research has examined the “disclosure reciprocity” effect, or the tendency for interaction partners to disclose intimate information in a reciprocal fashion. Social scientists have suggested that interaction partners may feel normative pressure or an obligation to reciprocate the intimacy level of information that is shared in the relationship. Failing to attend to the normative aspects of disclosure reciprocity can lead to relationship problems. For example, telling another person too much about oneself too early in a relationship or failing to reciprocate another person’s self-disclosures may inhibit the development of that relationship.

Researchers have consistently found that females tend to show more self-disclosure than males. Although a relatively small effect, this gender difference can be moderated by target, measure, or topic. For example, women disclose much more to those with whom they have a relationship (e.g., a friend or parent) than do men. Developmental researchers have found that as adolescents enter puberty, they disclose increasingly more to peers than to parents. Research also suggests that cultures with a greater emphasis on nuclear and extended families (e.g., Hispanic populations) are more self-disclosing than cultures with less closely knit social or family structures (e.g., non-Hispanic white Americans). Members of Eastern cultures (such as China and Japan) tend to report less frequent self-disclosures than members of Western cultures (such as the United States).

In addition to positive consequences for relationships, disclosing emotional self-related experiences has positive effects on physical health. However, sometimes disclosing a personal secret can lead to negative relationship consequences. For example, self-disclosures can make a person vulnerable to the rejection, indifference, alienation, or exploitation of others. In more applied settings, there is much discussion and debate about whether and to what extent therapists should self-disclose to their clients. The nature of self-disclosure in online relationships has also seen increased attention from researchers.

**SELF-EFFICACY**

Among all the thoughts that affect human functioning, and standing at the core of psychologist Albert Bandura’s social cognitive theory, are *self-efficacy* beliefs, the judgments that individuals make about their capability to accomplish tasks and succeed in activities. Self-efficacy beliefs touch virtually every aspect of people’s lives—whether they think productively or self-debilitatingly; how well they motivate themselves and persevere in the face of adversities; their vulnerability to stress and depression; and the life choices they make. People with a strong sense of efficacy approach difficult tasks as challenges to be mastered rather than as threats to be avoided. They have greater intrinsic interest and deep engrossment in activities, and they set themselves challenging goals and maintain strong commitment to them. High self-efficacy also helps create feelings of serenity in approaching difficult tasks and activities. As a consequence, self-efficacy beliefs powerfully influence the level of accomplishment that one ultimately achieves.

Self-efficacy should not be confused with self-esteem, which is a broad evaluation of one’s self, complete with the judgments of self-worth that accompany such evaluations. When individuals tap into these two self-beliefs, they ask themselves quite different types of questions. Self-efficacy beliefs revolve around questions of *can* (Can I drive a car? Can I solve this problem?), whereas self-esteem beliefs reflect questions of *feel* (Do I like myself? How do I feel about myself as a father?). Moreover, one’s beliefs about what one can do may bear little relation to how one feels about oneself. Many bright students are able to engage their academic tasks with strong self-efficacy even while their academic skills are a source of low self-esteem, having been labeled by their classmates as nerds or eggheads.

Individuals form their self-efficacy beliefs by interpreting information primarily from four sources, the most
influential of which is their past mastery experience. Successes typically raise self-efficacy; failures lower it. People also form their self-efficacy beliefs through the vicarious experience of observing the actions of models. Observing models contributes to the belief in one’s own capabilities: “If they can do it, so can I.” Individuals also create and develop their efficacy beliefs as a result of the social persuasions they receive from significant others. Finally, somatic and emotional states such as anxiety, stress, arousal, and mood provide information about efficacy beliefs. When people experience negative thoughts and fears about their capabilities, those affective reactions can lower self-efficacy perceptions and trigger additional stress and agitation that help ensure the inadequate performance they fear.

Because individuals operate collectively as well as individually, self-efficacy is both a personal and a social construct. Collective systems develop a sense of collective efficacy—a group’s shared belief in its capability to attain goals and accomplish desired tasks. For example, schools develop collective beliefs about the capability of their students to learn, of their teachers to teach and otherwise enhance the lives of their students, and of their administrators and policymakers to create environments conducive to these tasks. Organizations with a strong sense of collective efficacy exercise empowering and vitalizing influences on their constituents.

SELF-EMPLOYMENT

An individual who is self-employed works for himself or herself rather than as an employee of another individual or organization, obtaining an income through ownership of a business or professional practice in which he or she contributes much of the labor needed to produce or distribute a good or service. According to the Organization for Economic Cooperation and Development, the self-employed include employers, own-account workers, members of producers’ cooperatives, and unpaid family members. However, the designation “self-employed person” does not usually apply to those who are in a position to hire a large workforce (that is, to upper-management personnel who have a significant stake in the assets of the firm in which they are nominally self-employed). Such individuals are more appropriately referred to as “capitalists,” who derive their income primarily from ownership and investment rather than from the performance of labor. Since 1967 the Current Population Survey conducted by the U.S. federal government has asked self-described self-employed individuals whether the businesses they operate are incorporated. Those who answer affirmatively are deemed to be salaried employees; those who answer in the negative are defined as self-employed.

A self-employed person operating a small-scale, unincorporated business such as a family farm, a retail outlet, a service-contracting firm, or a professional practice may rely on the labor of assistants, whether waged or unwaged, in producing or providing a good or service, but most of the value added is contributed by the self-employed person. The self-employed include many farmers and professionals (e.g., medical doctors, dentists, lawyers, architects) as well as “freelance” workers such as writers, consultants, musicians, and artists who sell the products of their labor (rather than their ability to work) on the market, or who work on an “individual assignment” basis.

The developed capitalist world has seen a secular decline in the number of self-employed since the end of World War II (1939–1945). In 2005 the self-employed constituted 7.5, 12.4, and 14.7 percent of the labor force in the United States, Germany, and Japan, respectively. In the United States, as in most other industrialized countries, the downward trend in the self-employment rate is overwhelmingly attributable to the decline of small-scale agriculture and the movement of much of the self-employed farm population to waged and salaried employment, usually in nonagricultural sectors. However, the trend also reflects a more general decline of small and medium-sized businesses and the concomitant concentration of capital in large corporations. Changing tax laws have encouraged many small business proprietors to incorporate, with the consequence that they have been redefined as salaried employees. New corporate practices, such as franchising, have also had an impact on the measurement of self-employment.

Corporate downsizing, cutbacks in social assistance to the economically indigent, and efforts to reduce the size of the public sector since the profitability crises of the 1970s have contributed to a slowing or even a partial reversal of the long-term trend toward a decline in self-
employment. Although sometimes presented as a revival of “entrepreneurial spirit,” an increase in small-business activity may actually reflect the disappearance of “good” corporate or public-sector jobs for highly skilled, formerly salaried employees or for semiskilled or unskilled wage earners. During periods of high unemployment and underemployment, a spike in self-employment is likely to occur. In the 1990s, for example, Canada led the industrial nations in a “shift to self-employment” (with self-employment accounting for 18% of all employment by 1998) over a period in which unemployment and underemployment reached near-record levels (Lowe 2000).

Three additional empirical facts about self-employment deserve to be highlighted. First, self-employment is highest among those who are the most and the least educated, with the well educated typically receiving above-average earnings and the poorly educated below-average earnings, relative to employed workers. Second, the gender gap in earnings is greater between self-employed men and women than it is between their employed counterparts. And finally, the self-employed tend to put in longer hours for their earnings than do the employed, raising quality of life concerns that are magnified by their need to independently finance—or go without—the “benefits” (e.g., pensions, health care insurance, etc.) that are received by many employed workers.

At the ideological level, the persistence of self-employment (and small business in general) in the developed capitalist countries contributes significantly to obscuring the central dynamic of modern capitalism: the division, interdependence, and conflict between capital and wage labor. The self-employed, in Marxist terms, constitute a “petty bourgeoisie” within a global economy whose productive assets are decisively concentrated in the hands of several hundred huge transnational corporations that employ a tiny fraction of the world’s workforce. As such, self-employed persons are compelled to “exploit themselves” or face economic ruin. At the same time, their atomized existence, precarious competitive position, and sometime dependence on wage labor predispose them to embrace the ideological nostrums of “free enterprise” and “self-responsibility” to an extreme degree, to view the labor movement with suspicion or outright hostility, and to oppose more generous welfare-state policies.

In 2005 the self-employed constituted 34.9, 35.7, and 45.8 percent of the labor force in Brazil, Mexico, and Turkey, respectively. In the countries of the global South, the destruction of traditional subsistence agriculture and “independent commodity production” by export-led, neoliberal development has produced a new class of impoverished urban “entrepreneurs” struggling to survive with the most meager of economic assets. This phenomenon, which has taken on massive proportions in the barrios and shantytowns surrounding major Latin American cities, is a striking reminder that “self-employment” is very often a manifestation of chronic unemployment and underemployment, of which about one-third of the global labor force (1 billion people) were the victims in the year 2000.

SELF-ENHANCEMENT

Self-enhancement refers to an unduly inflated self-image and to the processes that make it so. As a process, self-enhancement is a motivated attempt to seek and emphasize positive feedback and to shield the self from negative feedback (where the shielding is more properly termed self-protection). Successful performance, social victories, or acceptance by others can be selectively recalled or embellished in memory, whereas failures, social defeats, or rejections can be reinterpreted, forgotten, or outright rejected. This operation of motivated self-enhancement is constrained by the motive of self-verification, which calls for the construction and maintenance of a stable self-image. The conflict between these two motives is apparent only when self-esteem is low. High self-esteem enables thoughts that are simultaneously self-enhancing and self-verifying. Hence, the process of self-enhancement can provide a buffer against depression (Bernichon, Cook, and Brown 2003).

Some processes of self-enhancement are conscious and strategic. Optimistic predictions regarding future events, such as a high perceived probability of succeeding at a job or a low perceived probability of contracting a dreaded disease, can be self-enhancing. When people care more about the hit rate of their predictions than about the false positive rate, self-enhancement may be the expression of rational decision utilities. These utilities are mal-
Self-Esteem

Predictions become more modest when people are accountable to others or when their actual outcomes are soon to be revealed. Mood states and the task difficulty also moderate predictions, such that a positive mood heightens self-enhancement and a difficult task lowers it.

Other processes are implicit or even unconscious. People with positive self-images automatically associate their own attributes with positive feelings and approach behavior. For example, the initials of one's own name and the date of one's birth come to be seen as highly desirable through repeated exposure. As a consequence, people like others who share these attributes, however irrelevant they might be for social behavior. When relocating, for example, people prefer to move to states whose names begin with the same letter as their own.

The prevalence of self-enhancement has spawned studies on stable individual differences. As a trait construct, self-enhancement is derivative because it is assessed as a discrepancy between the positivity of a person's self-image and some index of what the person is "really like." The idiographic approach is to ask people how they see themselves relative to the average person. This approach is problematic because many people who claim to be better than average may actually be better. The alternative approach is nomothetic in that it uses the discrepancy between a self-judgment and the aggregate judgment made by observers as a measure of self-enhancement. This method seeks to solve the criterion problem by statistical aggregation over observer judgments, assuming that observers are on average unbiased (Krueger 1998).

The methodological debate over how best to capture individual differences is bound up with the substantive question of whether self-enhancement is beneficial or detrimental to a person's well-being. This question remains open because the answer strongly depends on the method used. Idiographic studies suggest adaptive advantages, whereas nomothetic studies suggest that self-enhancers are narcissistic and disliked.

SELF-ESTEEM

Self-esteem is one of the most frequently studied constructs in the social sciences. Popular culture and public policy discussions also make frequent reference to self-esteem. Yet, despite its familiarity and wide usage, there is no generally accepted definition of self-esteem among social scientists. The earliest use of the term was by philosopher/psychologist William James in what became an influential chapter, "The Consciousness of Self," in The Principles of Psychology (1890). James included self-esteem in a group of "self-feelings" that emerge from the conscious awareness of self in relation to others. He offered two definitions of self-esteem that, in their inconsistency, typify the confusion and disagreement associated with the term. In the best-known of James's definitions, self-esteem is "determined by the ratio of our actualities to our supposed potentialities; a fraction of which our pretensions are the denominator and the numerator our success: thus, Self-esteem = Success / Pretensions" (p. 310). Alternatively, according to James, self-esteem is "a certain average tone of self-feeling which each one of us carries about with him, and which is independent of the objective reasons we may have for satisfaction or discontent" (p. 306). These seemingly incompatible definitions highlight a valid and important distinction between self-esteem that is contingent on circumstances and self-esteem that transcends them.

Most of the empirical research on self-esteem in the social sciences works from definitions similar to James's "average tone of self-feeling." The best-known of these is offered by the sociologist Morris Rosenberg in his Society and the Adolescent Self-Image, where self-esteem is defined as "a favorable or unfavorable attitude toward the self" (1965, p. 15). The brief self-report measure that Rosenberg developed for his research on adolescents, the Self-Esteem Scale, is the most widely used measure of self-esteem in social science research. In another influential book, The Antecedents of Self-Esteem, Stanley Coopersmith offered a similar conceptualization of self-esteem as "the evaluation the individual makes and customarily maintains with regard to himself" (1967, p. 4). Both Rosenberg and Coopersmith operate from the assumption that people's attitude toward or customary evaluation of self underlies their overall sense of self-worth. The definitions offered in these two classic works and assumed by much of the empirical work on self-esteem describe a particular form of self-esteem that is traitlike, consistent across time and situations, and global, concerned with all aspects of the self. This definition also corresponds well to usage of the term in popular culture and public policy settings.

Two alternative conceptualizations of self-esteem depart from these classic definitions by dropping the
assumption that self-esteem is global or that it is a trait. Domain-specific conceptualizations accept the premise that self-esteem is an attitude toward or customary evaluation of the self but contend that it is not necessarily global. Thus, for instance, it is possible to have a high opinion of oneself in the social domain but a relatively modest, or even negative, opinion of oneself in the academic domain. Whether self-esteem is viewed as global or domain-specific, it may be conceptualized as a state rather than a trait. This form of self-esteem is like James’s ratio of successes to pretensions definition in that it is contingent on circumstances. State self-esteem typically rises when circumstances are positive and drops when they are negative. Neither the domain-specific nor the state conceptualizations are necessarily inconsistent with the global trait conceptualization because it can be shown that weighted combinations of domain-specific self-evaluations are highly predictive of global self-esteem and that state self-esteem varies in a relatively narrow range around the level of trait self-esteem to which it typically returns.

Classic conceptualizations of self-esteem and the questionnaire measures they have spawned assume that people are willing and able to accurately report their self-esteem, an assumption that now seems at least partially unfounded. Drawing on basic research on attitude formation and change, social scientists now make a distinction between self-esteem as traditionally measured—explicit self-esteem—and self-esteem measured using procedures that do not require or allow people to consciously indicate their attitude toward themselves—implicit self-esteem. As with attitudes toward any object, research indicates that explicit and implicit attitudes toward self are not strongly associated. Indeed, different patterns of correspondence between explicit and implicit self-esteem are now viewed as evidence of qualitatively different forms of self-esteem. For instance, a person who is high on explicit but low on implicit self-esteem is described as having defensive self-esteem. A person who is high on explicit and implicit self-esteem is described as having genuine self-esteem. This work raises questions about the likely success of policies and practices designed to bolster self-esteem that focus only on explicit attitudes toward self (e.g., positive “self-talk”).

Furthermore, other important qualitative distinctions in self-esteem indicate that there is more to self-esteem than whether it is high or low. One such distinction is stability of self-esteem, defined as the degree of variability in a person’s self-esteem across time. Stability of self-esteem is only modestly associated with level of self-esteem, meaning that people at any given level of self-esteem will vary in the stability of their self-esteem. The combination of level and stability of self-esteem allows for more precise predictions about the role of self-esteem in behavior. For instance, people with high but unstable self-esteem are more likely to react with hostility to provocation than people with stable high self-esteem. Another qualitative distinction is contingency of self-esteem, defined as the degree to which self-esteem is responsive to changes in circumstances. Contingency is moderately correlated with level of self-esteem, indicating that lower self-esteem is accompanied by greater contingency. Contingency of self-esteem typically is indexed at the domain-specific level, allowing for distinctions between people not only in terms of how contingent their self-esteem is, but also in terms of the specific domains in which it is contingent.

In popular usage, self-esteem often is used as a generic label for a variety of similar constructs from which it should be distinguished. Principal among these is self-concept, a much broader term that, according to Rosenberg, is “the totality of the individual’s thoughts and feelings having reference to himself as object” (1965, p. 7, emphasis in original). Another construct often erroneously referred to as self-esteem is self-efficacy, a narrower construct than self-esteem—even in its domain-specific form—that reflects people’s perceptions of their ability to enact a specific behavior. It is directly influenced by prior experience with the behavior and is only indirectly influenced by or reflective of self-esteem.

In popular culture and public policy settings, self-esteem is perceived as critically important to healthy functioning. The strength of this perception is evident in the efforts of groups such as the National Association for Self-Esteem and the California Task Force to Promote Self-Esteem and Personal and Social Responsibility, the latter concluding that “self-esteem is the likeliest candidate for a social vaccine” (1990, p. 232). This conclusion stands in stark contrast to the empirical research literature, which indicates that self-esteem is not strongly associated with behavior—desirable or undesirable—and that, when there is an association, self-esteem is not a causal factor. In an influential Scientific American article, “Exploding the Self-Esteem Myth,” Roy Baumeister and colleagues summarized this literature by stating, “we have found little to indicate that indiscriminately promoting self-esteem in today’s children or adults … offers society any compensatory benefits” (2005, p. 91). This conclusion has led social scientists to examine more closely their assumptions about the origins and functions of self-esteem. Emerging accounts suggest that self-esteem is best viewed as a reflection of other characteristics such as healthy family relationships and social acceptance; it is these constructs that warrant the attention given to self-esteem.

Self-esteem is at once simple and complex. The widely accepted definition of the construct as simply people’s attitude toward themselves is at odds with the social and psychological structures and processes that underlie it, as well as the wide range of opinions as to its impor-
Self-Fulfilling Prophecies

tance for individuals and society. Concerns about whether it is important at all have inspired social scientists to probe more deeply the origins and underpinnings of self-esteem to determine how, if at all, it matters. The result is one of the most richly described, frequently studied, and intriguing constructs in the social sciences.

SELF-FULFILLING PROPHECIES

Psychological theory proposes that people’s beliefs construct reality. The emphasis on the construction of reality dates back to the 1940s and 1950s. During this time, “New Look in Perception” research challenged the idea that people perceive reality accurately by proposing that what people perceive is heavily influenced by their motives, emotions, and expectations. The self-fulfilling prophecy is a quintessential process of this perspective because it involves people’s beliefs changing social reality. A self-fulfilling prophecy occurs when one person causes her or his own false belief about another person to become true.

A self-fulfilling prophecy includes three steps. First, one person must hold a false belief about another person. For example, a teacher may overestimate a student’s ability, believing that the student is more capable than the student really is. Second, the person holding the false belief must treat the other person in a manner that is consistent with it. A teacher who overestimates a student’s ability would have to treat the student as if she or he is highly capable. The teacher may often call on that student, spend extra time with that student, teach that student especially difficult material, and provide that student with feedback contingent on performance (Rosenthal 1973). Third, the person about whom the false belief is held must, in response to the treatment she or he receives, confirm the originally false belief. The student who is treated as if she or he is highly capable may enjoy and value school and, consequently, invest more time and effort on school work than other students do. In turn, this student may ultimately learn more than other students in the class, thereby confirming the teacher’s originally false belief that she or he was highly capable.

The term self-fulfilling prophecy was introduced to the social sciences by Robert Merton (1948). A sociologist by training, Merton proposed that the self-fulfilling prophecy was capable of creating large-scale social problems such as social inequalities. For example, he described how in the early part of the twentieth century African Americans were barred from joining labor unions on the grounds that they were strikebreakers. This left African American laborers with few job opportunities, forcing them to take any work that presented itself, including work that became available as a result of white laborers going on strike. Thus, according to Merton, the belief that African Americans were strikebreakers caused them out of necessity to become strikebreakers, thereby creating a self-fulfilling prophecy.

SELF-FULFILLING PROPHECY RESEARCH

Merton’s contribution to the field’s understanding of the self-fulfilling prophecy was purely theoretical, meaning that he explained how self-fulfilling prophecies may operate, but never actually tested whether they occur. Nonetheless, his analysis resulted in hundreds of experimental tests of the process that have provided clear evidence that the self-fulfilling prophecy is a real phenomenon that occurs in a variety of settings.

For example, Robert Rosenthal (a professor at Harvard University) and Lenora Jacobson (an elementary school principal in San Francisco) tested whether teachers’ false beliefs about their students’ intelligence create self-fulfilling prophecies. Rosenthal and Jacobson (1968) were concerned that one reason disadvantaged students may perform poorly in school is because that is what their teachers expect of them, and they wondered if disadvantaged students might perform better if their teachers expected them to improve academically. To test this, they told elementary school teachers that Harvard researchers had created a new IQ test that could identify “intellectual blooming.” They then told the teachers which of their students had been identified by this test as one of these “late

414 INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION
bloomers”—students who would have substantial gains in their IQs over the course of the school year. In reality, there was no special test to measure intellectual blooming; students had simply been administered a typical IQ test, and random assignment determined which students would be labeled as the late bloomers. Because the late bloomers were chosen at random, they were really no different from any other students intellectually. The only difference between the students labeled late bloomers and those not so labeled was their teachers’ expectations for them. Therefore, any difference between their IQs at the end of the school year could be attributed only to a self-fulfilling prophecy, which is exactly what Rosenthal and Jacobson found. By the end of the school year, the late bloomers had significantly greater gains in their IQs than did the other students.

THE MAGNITUDE AND IMPLICATIONS OF SELF-FULFILLING PROPECIES

The large body of research on self-fulfilling prophecies shows that people’s false beliefs can influence the behavior of others. However, the magnitude by which they do so is usually modest, meaning that, on average, people’s false beliefs only influence other people’s behavior through self-fulfilling prophecies a little bit. Even so, there are conditions under which self-fulfilling prophecy effects are larger than average. For example, self-fulfilling prophecy effects are strongest among individuals who are stigmatized, including African American students, girls in math classes, students who are tracked into low-ability groups within their classrooms, and students who have histories of poor academic achievement (Jussim, Eccles, and Madon 1996).

Self-fulfilling prophecy effects can also become larger than average through a process of accumulation. In a typical day an individual interacts with many people, each of whom may hold a false belief about that individual and have a self-fulfilling effect on that individual’s behavior. When the false beliefs that different people hold about the same individual are similar, their independent self-fulfilling effects may combine, thereby causing small self-fulfilling prophecy effects to become large. Consistent with this process, research has shown that parents have the strongest self-fulfilling effects on their children’s alcohol use when both hold false and unfavorable beliefs about their child’s likelihood of drinking alcohol (Madon, Guyll, Spoth, and Willard 2004). The accumulation of self-fulfilling prophecy effects across people has particularly important implications for stereotyped individuals because such individuals are disproportionately exposed to false and unfavorable beliefs from many different people.

Although any single person’s stereotypic beliefs may have only a small self-fulfilling effect on another’s behavior, that effect may combine with the self-fulfilling effects of other people’s stereotypic beliefs to ultimately have a large and harmful impact on the outcomes of stereotyped individuals such as women and minorities.

SELF-GUIDES

Self-guides are constructs in social psychology that refer to representations of the self. Self-guides are desired self states that have motivational implications and are involved in the process of self-regulation.

The various types of self-guides, proposed by psychologist E. Tory Higgins (1987), are the actual self, the ideal self, and the ought self. The actual self refers to the way individuals view themselves currently. The ideal self refers to the person that individuals would like to be, and the ought self refers to the person that individuals feel they should be. Individuals’ ideal self-guides tend to be associated with hopes and wishes, while their ought self-guides tend to be concerned with safety and responsibility. These ought self-guides represent the internalization of expectations of others and society.

The source of self-guides can also be distinguished as being from the self or from an other. For instance, an indi-
individual might have a self-guide that represents who he would ideally like to be, as well as a self-guide that represents who his father thinks he ought to be.

Comparisons can occur between any of these self-guides. Individuals may compare their own ideal selves with others’ ideal selves for them. Or they may compare their own actual self with their own ought self-guide. It is through these comparisons that self-guides are associated with self-regulation. Individuals may experience a discrepancy between their actual self and either their ought or ideal self. Such discrepancies lead to the experience of negative affect. It is assumed that this experience of negative affect motivates individuals to change their behavior in the hopes of reducing the discrepancy between their actual self and a self-guide. A reduction in this discrepancy then leads to a reduction in the experience of negative affect. Successful self-regulation is equated with lacking a discrepancy and is associated with experiencing positive affect. Failure to self-regulate is equated with experiencing a discrepancy and is associated with negative affect.

Research has found that the positive and negative affect experienced can be differentiated by the type of self-guide used in comparison. Discrepancies between actual selves and ideal selves are associated with depression-related affect, such as depression and sadness. Discrepancies between actual selves and ought selves are associated with agitation-related affect, such as anxiety and guilt.

Individuals may differ in regard to the type of self-guide that is chronically accessible for them. These differences carry implications for goal pursuit and information processing. Higgins (1997) expanded his theory to suggest that individuals with chronic ideal self-guides tend to pursue goals that are related to promotion or growth, whereas individuals with chronic ought self-guides tend to pursue goals that are related to prevention or safety. Lisa Evans and Richard Petty (2003) show that individuals pay more attention to and more thoroughly process information that is presented in a way consistent with their more prevalent self-guide.

SELF-HATRED

Much of the psychological research in the area of self-hatred owes its origin to the work of the American philosopher and social psychologist George Herbert Mead (1863–1931) and his idea of the “looking-glass self.” Mead claimed that people pay attention to the view that others have of them, and when that view is largely negative, a person can internalize it and develop self-hatred. Mead’s other major contribution to this area of social research was the importance he placed on the role that language and symbols play in society. A number of later researchers pointed out that American symbols were major conveyers of negative views of blacks and other ethnic groups. At least one prolific author, Sander L. Gilman, has gone so far as to suggest that persecution is inherent in a society’s language. Erving Goffman (1922–1982), another influential sociologist, claimed that ethnic (and other minority) groups were often “stigmatized” by society’s negative symbolic interaction and the internalization of such stigmatization (often termed “racism”) is a major cause of self-hatred.

There is, however, some controversy among scholars concerning the degree to which ethnic group identity affects the development of self-hatred. Some researchers take the position that mere membership in an ethnic group, whether freely chosen or not, is sufficient to cause the individual member to develop feelings of self-hatred if the group is negatively viewed by the majority group. Other researchers take the position that it is not group membership per se that results in self-hatred but the degree to which the individual identifies with the group in question. High or strong identification with one’s own ethnic group can sometimes block or ameliorate the kind of psychological damage that results in self-hatred. Ethnic group membership can thus be viewed as a protection against self-hatred as opposed to a cause.

Because of their unique experiences with racism and oppression, blacks and Jews have been the populations most heavily studied in the area of self-hatred. Many of the early researchers were themselves Jews who sought to understand the people in their communities who exhibited visible signs of self-hatred. The founder of psychoanalysis, Sigmund Freud (1856–1939), wrote *Moses and Monotheism* in part to explain Jewish self-hatred produced by external oppression in Europe during the 1930s. The “self-hating” or “self-loathing” Jew has become an archetype in modern American social science, as the term is often used to disparage those Jews who are viewed as anti-Zionist or anti-Israel or for any Jew who is “not Jewish enough.” A similar term, “Uncle Tom,” has been used to describe the African American who is deemed to possess a high degree of self-hatred. (The term *Uncle Tom* comes from the title character of Harriet Beecher Stowe’s antislavery novel *Uncle Tom’s Cabin.*) Apples, bananas, and coconuts...
are terms that have been used to describe people whose external features are nonwhite (red, yellow, and brown respectively) but whose internal thought patterns are said to be white and reflective of a high degree of self-hatred. The individuals who are the recipients of such negative appellations defend themselves by claiming that it is possible to assimilate some values of the dominant society while at the same time rejecting those (such as white superiority) that they find offensive. Research in support of the possibility of such selective socialization is sparse.

The feminist-oriented research in this area is a reminder that self-hatred is not restricted to members of marginalized groups or subcultures. It is found in the wider society and has been linked to symptoms of depression, substance abuse, and general anxiety. What is perhaps unique about this type of self-hatred is that it does not seem to be related to anything other than a sense of personal failure. It has proven difficult, if not impossible, for researchers to specify a causal link among the possible variables. Self-hatred is as much a cause of as well as a result of depression, anxiety, substance abuse, and gender ambiguity. It can therefore be viewed as both the hub and a spoke of the wheel of social misfortune. As a hub it represents the central role that the self, however damaged or elevated, plays in the dynamics of social life. As a spoke self-hatred represents one of the negative consequences of the socialization process itself.

SELF-IDENTITY

The notion of the social self has been of particular interest in the social sciences because it reflects a concern with how people's social behavior varies not only as a function of different social roles but also as a function of the kind of social others with whom a person interacts. Within the social sciences, a distinction is made between personal identities, self-identities, and social identities (Hogg, Terry, and White 1995; Thoits and Vinh 1997). Personal identities consist of self-definitions in terms of unique and idiosyncratic characteristics. Social identities, on the other hand, reflect identification of the self with a social group or category. Self-identities, the focus of this article, are conceptualized as a definition of self as a person who performs a particular role or behavior.

Self-identity refers to a person's self-conception, self-referent cognitions, or self-definition that people apply to themselves as a consequence of the structural role positions he or she occupies or a particular behavior he or she engages in regularly. Self-identities reflect the "labels people use to describe themselves" (Biddle, Bank, and Slaving 1987, p. 326). For example, a person's self-identities may include the fact that she is a mother, a wife, a daughter, a social worker, and a blood donor. Self-identities provide meaning for the self, not only because they refer to concrete role specifications or behaviors but also because they distinguish roles or actions from counterroles or opposing behaviors (Lindesmith and Strauss 1956). For example, "the role of mother takes on meaning in connection with the role of father, doctor in connection with nurse, and so on" (White and Burke 1987, p. 312).

Theoretically, the importance of the concept of self-identity is derived from identity theory (Stryker 1968, 1980; Burke 1980; Stryker and Serpe 1982; Wiley 1991), which views the self not as an autonomous psychological entity but as a multifaceted social construct that emerges from people's roles in society and the behaviors they perform. Symbolic interactionists such as Mead (1934) and Cooley (1902) considered the self to be a product of social interaction: It is through social interaction that identities actually acquire self-meaning and people come to know who they are. It is important to note that identity theory focuses on the self-defining roles that people occupy in society rather than on the wider range of different social attributes, such as gender, race, or ethnicity, that can be ascribed to the self. Thus, the general perspective of identity theory forms the basis for a relatively large body of microsociological literature concerned with predicting role-related behavior (Simon 1992; Thoits 1991). Within social psychology, however, researchers have been more interested in using self-identity to improve our understanding and prediction of the relationship between attitudes and action.
The concept of self-identity is pivotal in the link between social structure and individual action. Self-identities, by definition, imply action (Callero 1985) and are a set of expectations prescribing behavior derived from a person's social position and considered appropriate by others. Satisfactory enactment of roles or behaviors not only confirms and validates a person's self-identity (Callero 1985), it also reflects positively on self-evaluation. The perception that one is enacting a role satisfactorily should enhance feelings of self-esteem, whereas perceptions of poor role performance may engender doubts about one's self-worth and may even produce symptoms of psychological distress (Thoits 1991; Hoelter 1983; Stryker and Serpe 1982).

**THE APPLICATION OF SELF-IDENTITY IN THE ATTITUDE-BEHAVIOR RELATIONSHIP**

Within the field of social psychology, the greatest interest in self-identity has been shown by researchers in the attitude-behavior field. Within this field, it has been argued that self-identities can determine intentions and behaviors. For example, political activists may participate in protest actions because activism has become a central part of their self-concepts, and blood donors may give blood because being a donor has become an important part of their self-definition. Self-identity may have a predictive effect on intentions, independent of attitudes and other constructs, because self-identity encapsulates people's goals or interests that are distinct from those expressed by their attitudes. Indeed, as noted by Sparks (2000), the integration of self-identity into the theory of planned behavior "offers the opportunity to examine the social, moral, and emotional dimensions of people's attitudes and behaviour in greater detail" (p. 45).

Several authors have addressed the extent to which self-identity might be a useful addition to the dominant models of the attitude-behavior relationship, namely the theories of reasoned action (Fishbein and Ajzen 1974) and planned behavior (Ajzen 1991). Self-identity has been found to contribute significantly to the prediction of behavior across a number of domains, including altruistic behavior such as blood donation (Charng, Piliavin, and Callero 1988), political behavior such as voting (Granberg and Holmberg 1990), environmental behavior such as recycling (Terry, Hogg, and White 1999), health behaviors such as exercise behavior (Theodorakis 1994) or licit and illicit drug use (Conner and McMillan 1999), and consumer behavior such as food choice (Sparks and Shepherd 1992). On the basis of past research, Conner and Armitage (1998) argued that it is reasonable to assume that there are certain behaviors for which self-identity is an important determinant of intentions (Armitage and Conner, 2001).

**THE INTERPLAY BETWEEN SELF-IDENTITY AND PAST BEHAVIOR**

One important question for self-identity researchers is the nature of the interplay between self-identity and past behavior. Identity theory assumes that self-identity and past behavior interact to influence intentions. That is, with repeated performance of a behavior, that behavior is more likely to be seen as an important part of the self-concept, increasing the predictive power of self-identity. However, support for this hypothesis has been equivocal: Some studies have found that self-identity is more predictive of intentions at higher levels of past behavior (Charng et al. 1988), some tests have found no evidence that the effects of self-identity vary as a function of past performance of the behavior (Astrom and Rise 2001; Terry et al. 1999), and other tests have found that self-identity is more predictive of intentions at lower levels of past behavior (Conner and McMillan 1999; Fekadu and Kraft 2001). Conner and McMillan argued that the stronger impact of self-identity on intention at lower levels of past behavior may reflect the role that initial experiences play in strengthening the relevance of identity to intentions. However, as behavior is repeated, intentions become less under the control of cognitive factors such as self-identity and more under the control of habitual forces such as past behavior. Given these inconsistencies, more research on the interplay of self-identity and past behavior, using a wide range of populations and behaviors, is needed in order to understand more fully the role of self-identity in the attitude-behavior context.

**ASSESSING SELF-IDENTITY**

Within the literature, self-identity is assessed in a number of ways. Initially, researchers used direct and explicit statements to measure the extent to which a particular role or behavior was integrated as part of the self. For example, researchers working within the theory of planned behavior have asked people to indicate their level of agreement with statements such as, "I think of myself as the sort of person who is concerned about the long-term health effects of my food choices" (Sparks and Guthrie 1998). "Blood donation is an important part of who I am" (Charng et al. 1988), or "I am not a type of person oriented to engaging in contraception" (Fekadu and Kraft 2001). Such measures have been found to be reliable and to predict behavioral intention; however, several criticisms have been noted. First, explicit statements require people to declare in public his or her identification with a particular role and behavior, therefore increasing the salience of that behavior (Sparks, Shepherd, Wieringa, and

---

**Notes:**

Zimmermanns 1995). Second, it has been argued that measures of self-identity serve as measures of past behavior, with people possibly inferring their self-identities from an examination of their past behavior (Sparks 2000). Finally, Fishbein (1997) has argued that self-identity measures may essentially constitute measures of behavioral intention.

In the past decade, however, researchers have developed alternate measures of self-identity. Drawing on marketing research, Mannetti and colleagues (2002, 2004) have used an identity-similarity measure that reflects the degree of similarity between the person’s self-image and that of the stereotypical or idealized person who engages in the target behavior. After obtaining independent descriptions of the two images, the distance or nearness between them is computed as a difference score, which is then used as an identity-similarity measure. This type of measure, which is less direct and explicit as well as more specific than other measures, does not increase the salience of behavior, and is independent of behavioral intention, has been found to be a large and significant predictor of behavioral intention (Mannetti, Pierro, and Livi 2002, 2004).

FUTURE DIRECTIONS

Theory and research within the social sciences has highlighted the important role that self-identities play in shaping and guiding action, but future research is needed to tease apart its specific roles. One important direction for future research is to examine the interplay among self-identity and other constructs identified as important in attitude-behavior research and to track the development of self-identities over time. Another important research direction, given the criticisms leveled at self-identity measures, is to develop measures that avoid both the conceptual issues highlighted above and the statistical issues involved in using difference scores. Interest in self-identity and its implications for behavior is widespread, and it is likely that interest in this area will persist for a long time.

SELF-JUSTIFICATION

People are rational beings, highly capable of exercising careful judgment and judicious evaluation before taking action. Research shows that people are often rationalizing creatures as well, quite facile in their ability to justify their own actions, beliefs, and feelings after the fact. This phenomenon, known as self-justification, involves convincing oneself (and others) that what one did, felt, or thought was logically appropriate, even going so far as to invent plausible explanations when it is not immediately apparent why one acted, felt, or thought as one did.

The research that first brought attention to people’s tendency to self-justify was a study of the rumors that arose after an earthquake in India in the 1930s. The report noted a perplexing pattern of rumor transmission: Individuals who lived in an area minimally affected by the devastating event were the ones spreading various stories of future calamities. Why would people who suffered little or no negative effects of the earthquake engage in concocting and communicating ideas that would seemingly only provoke fear and dread? Upon reflecting on these findings, social psychologist Leon Festinger (1919–1989) had the insight that this behavior was not fear-provoking in nature, rather it was fear-justifying. Festinger reasoned that although these individuals were spared the worst of the earthquake, they nonetheless were afraid. Yet the circumstances in their case, having escaped disaster, could not adequately or fully account for the anxiety they were experiencing, which Festinger argued motivated them to create future bleak scenarios that were more commensurate with the dread they already felt, and thus served to justify it.

Festinger went on to develop his cognitive dissonance theory, which provided a conceptual basis for this and other instances of self-justification phenomena. He argued that people have a need for their cognitions (i.e., thoughts, beliefs, and attitudes) to be consistent with one another. When people become aware that an inconsistency exists among two or more cognitions, an unpleasant tension state known as cognitive dissonance arises. People are motivated to reduce the dissonance and do so by changing old, or adding new, cognitions to eliminate the inconsistency.

One of the earliest tests of cognitive dissonance theory and possibly the first systematic demonstration of self-justification consisted of research participants working on an extremely boring task—turning wooden knobs again and again—and then being asked to convince another person that the task was actually quite enjoyable. Participants were offered either $1 or $20 as compensation for agreeing to this latter request, which they all did. Later, participants provided their own evaluation of the knob-turning task. Participants who were promised $20

SELF-IMAGE

SEE Body Image; Self-Concept.

SELFISHNESS

SEE Generosity/Selfishness.
to convince another person that the knob-turning task was a pleasant experience rated the task very negatively, no different in fact than another group of participants who performed the task but were not asked to misrepresent it to someone else. Those promised $1, however, rated the knob-turning task more positively than did the other two groups of participants. In explaining this result, Festinger and his colleagues argued that unlike $20, $1 in compensation was not psychologically sufficient to justify the discrepancy between what participants really felt about the dull task and their contrary public expression that the task was enjoyable. To diminish this contradiction, and the corresponding dissonance associated with it, participants altered their attitude toward the knob-turning task in a positive direction. Participants' public expression that the task was interesting was now better justified by their "corrected" attitude.

Later research demonstrated that self-justification helps explain the ubiquity of initiation rituals across human cultures. Elliot Aronson and Judson Mills had participants undergo either a severe, mild, or no screening session (effectively serving as an initiation) before being allowed to take part in what was anticipated to be an interesting discussion on the psychology of sex. All participants then listened to a portion of an ostensibly ongoing group discussion of secondary mating habits in lower animals, which was designed to be dull and banal. Finally, participants were asked to provide their reactions to the discussion and group. Participants who underwent the severe initiation, which required them to exert the most effort and endure the most suffering to gain admittance to the group, expressed more positive reactions than did those who experienced only a mild initiation or no initiation at all. Aronson and Mills argued that the severe initiation was too painful for participants to deny; hence they justified their exertions (simultaneously reducing dissonance) by inflating their estimate of the attractiveness of the group. This particular type of self-justification is often referred to as effort justification.

A particularly troubling manifestation of self-justification occurs when people engage in what has become known as victim derogation or defensive attribution. When we observe bad things happening to good people for no apparent reason, we tend to rationalize that they must have had it coming. Blaming the victim enables us to maintain the perception that the world is a just place in which random victimization does not occur. Similarly, perpetrators of harm often belittle their victims in order to convince themselves that the victims deserved exactly what they got.

SELF-MONITORING
Self-monitoring is a construct referring to individual differences in the way people monitor and manage their presentations of self, behaviors, and emotions. It was first proposed by psychologist Mark Snyder in 1974 in his article “Self-Monitoring of Expressive Behavior.” According to Snyder’s formulation, people vary in the degree to which they attend and respond to social and situational cues regarding what behaviors are most appropriate. Essentially, variations in self-monitoring refer to variations in how willing or able people are to regulate their behavior and self-presentations in specific situations.

The Self-Monitoring (SM) Scale, developed by Snyder, captures differences in the kinds of cues to which individuals respond. It consists of items assessing how respondents observe, control, or regulate their expressive behavior in different settings. While there were twenty-five true-false items in the original scale, a revised eighteen-item scale is now more frequently used by researchers.

Individuals who score high on the SM Scale (high self-monitors) are concerned with the situational appropriateness of their behavior and are sensitive to social cues about what is correct behavior. They would agree with a scale item like “I would probably make a good actor.” Regardless of how he or she really feels, a high self-monitor might be one of the most mellow of the mourners at a funeral held in the morning and then one of the happiest people at a party or wedding held later that same day. In contrast, those scoring low on the SM Scale (low self-monitors) are controlled more by their perceived internal feelings and attitudes and make little effort to fit the social
Self-Perception Theory

situation. They would agree with a scale item like “I have trouble changing my behavior to suit different people and different situations.” Low self-monitors might find it hard to hide their good mood even at a funeral. Alternatively, low self-monitors are more likely to show unhappiness at a party if they happen to be in a bad mood that day.

A great deal of research has examined behavioral differences between the two self-presentational orientations. For example, high self-monitors show greater cross-situational variability in their behavior than low self-monitors. Alternatively, low self-monitors are more likely to show high correspondence between inner attitudes and overt behaviors than are high self-monitors. These differences reflect the fact that high self-monitors are more likely to monitor their social environments, whereas low self-monitors are more likely to monitor themselves. Thus, it follows that among high self-monitors, aspects of the social self are more important, whereas the existential, experiential self (i.e., how one experiences oneself) is more important to the low self-monitor.

With regard to how these two self-types are related to psychological health, Snyder considers high self-monitors to be more pragmatic (or sensitive and strategic) across a number of social situations. Low self-monitors, on the other hand, tend to be more consistent with their principles and less responsive to situational or social pressures. Research suggests that personal problems are no more common among high or low self-monitors and that neither type is more susceptible to mental illness. Self-monitoring also seems to be unrelated to measures of neuroticism, anxiety, and depression.

SELF-PERCEPTION THEORY

Psychology has long recognized that people must know themselves in order to survive and adapt in life. The value of self-knowledge stems from the fact that the self represents the only constant throughout life. Because of this if the self is well defined, it can provide a solid basis of values, preferences, and attitudes to manage the many decisions of daily life. Clear self-knowledge helps people to quickly decide and express their views on issues such as capital punishment, the ideal profession, or their tastes in music, whereas the absence of clear self-knowledge can leave an individual paralyzed by these decisions. Given the importance of self-knowledge, psychologists have spent a great deal of time attempting to understand how people come to know themselves.

Self-perception theory represents one of the most influential theories of how self-knowledge unfolds. Developed by social psychologist Daryl Bem self-perception theory consists of two basic claims. First the theory claims that people come to know their own attitudes, beliefs, and other internal states by inferring them from their own behavior and the circumstances under which they occur. So a student who observes that he or she constantly reads psychology books may infer an interest in psychology. Second the theory claims that when internal cues are weak, the individual is in the same position as an outside observer who must rely upon the external cues of their behavior to infer their own inner characteristics. In this case people's conclusion that they genuinely like psychology will be reinforced if there are no external incentives to explain their behavior (e.g., grades), and they have no clear prior opinions regarding psychology. Thus people simply use their behavior and the circumstances in which it occurs to infer their own beliefs and attitudes.

One reason why self-perception theory has been so influential stems from its simplicity as an explanation for how self-knowledge develops. That is people come to know themselves merely by observing their own behavior. Beyond its simplicity, however, self-perception theory has been so influential because it provides an important contrast to the most famous psychological theory of how behavior shapes self-knowledge: cognitive dissonance theory. Cognitive dissonance theory assumes that people are motivated to maintain consistency between self beliefs and experience an unpleasant state of dissonance when they hold two inconsistent beliefs about the self. Thus the inconsistency between the thoughts “I do not like psychology” and “I constantly read about psychology” arouses dissonance, and people are motivated to reduce dissonance by changing one of those thoughts. The most direct way to resolve dissonance is to change the prior belief (“I do not like psychology”) to align with the behavior (“I spend a great deal of time learning about psychology”). That is the person can resolve dissonance by making their initial attitude more favorable (I really do like psychology) and, hence, consistent with their behavior.

There are two differences between cognitive dissonance theory and self-perception theory. First unlike cog-
nitive dissonance theory, self-perception theory does not assume that any motivational state (e.g., dissonance reduction) is necessary for change in self-knowledge. In fact self-perception theory only requires people's willingness to infer their own attitudes and beliefs by considering the environmental and dispositional causes for their own actions for changes in self-knowledge to occur. Second self-perception theory claims that people can use their own behavior to infer self-knowledge when the internal cues of prior beliefs are ambiguous or weak, whereas cognitive dissonance theory assumes that people adjust self-knowledge only when the internal cues of prior beliefs are clear and conflict with their freely chosen behavior. Taken together these two differences have led psychologists to suggest that both self-perception theory and cognitive dissonance theory can explain the adjustment of self-knowledge under different conditions. Self-perception theory explains the creation of new self-knowledge following behavior that does not conflict with clear initial self-views whereas cognitive dissonance explains change in existing self-knowledge following freely chosen behavior that does conflict with clear initial self-views.

The resolution of the self-perception theory versus cognitive dissonance theory debate represents one of the greatest contributions of self-perception theory. Indeed psychology only becomes better when old theories are challenged and complemented by new theories. However the contribution of self-perception theory extends beyond cognitive dissonance theory through its ability to account for a wider variety of self-attribution phenomenon. Most notably self-perception theory can explain how people develop self-knowledge from behavior even when there is no inconsistency between prior beliefs and behavior. So self-perception theory can explain how people infer that they intrinsically enjoy engaging in an activity (psychology) that they once found intrinsically unenjoyable (behavior-belief inconsistency) when there are not obvious situational incentives to explain their behavior (e.g., money for grades). In addition, however, self-perception theory can explain how people infer that they do not intrinsically enjoy engaging in an activity (psychology) that they once found intrinsically enjoyable (behavior-belief consistency) when there are obvious situational incentives that can explain their behavior (e.g., money for grades). Cognitive dissonance theory cannot explain this type of change in self-views because the behavior of task engagement (reading psychology) is not inconsistent with the initial belief that they enjoy the task. Self-perception theory can explain this type of change in self-beliefs because it does not assume that an inconsistency must exist between initial beliefs and behavior for people to adjust self-knowledge. That is people infer that they must be engaging in the task to earn the external rewards rather than to satisfy their intrinsic interest in the activity. Self-perception theory not only explains the change in self-views produced by external rewards that cannot be explained with cognitive dissonance but also emphasizes the dangers of offering people incentives to engage in tasks that they are already interested in. The ability to explain changes in self-knowledge under a wide range of conditions makes self-perception theory one of the most influential theories of how people get to know themselves.

SELF-PRESENTATION
Self-presentation is the process by which individuals represent themselves to the social world. This process occurs at both conscious and nonconscious (automatic) levels and is usually motivated by a desire to please others and/or meet the needs of the self. Self-presentation can be used as a means to manage the impressions others form of oneself. Strategic or tactical self-presentation (impression management) occurs when individuals seek to create a desired image or invoke a desired response from others.

The concept of self-presentation emerged from the symbolic interactionist (SI) tradition. The SI tradition is a uniquely sociological contribution to the field of social psychology that attends to the processes by which individuals create and negotiate the social world. SI proposes that it is through interaction and the development of shared meanings (symbolism) that individuals navigate the social world. The works of Erving Goffman, especially The Presentation of Self in Everyday Life (1959), exemplify the SI tradition and are seminal contributions to the study of impression management and self-presentation.

Goffman employs a dramaturgical metaphor in which he maps elements of social interaction to the stage. Working at the microsociological level, Goffman focused on the process by which actors construct roles and portray them to an audience. The social actor works to create a front that is both believable and elicits the approval of others. Goffman's
work on impression management and self-presentation provides a roadmap for understanding human behavior and the tension between the individual and society.

Subsequent to Goffman’s early articulations of ideas of self-presentation, experimental social psychologists such as Edward E. Jones and Barry R. Schlenker devised experimental methods for the study of self-presentation. This fruitful work provided empirical data about self-presentation that fueled the development of theoretical accounts of self-presentation (e.g., Schlenker 1975). Jones’s important text Ingratiation presented ingratiation as a form of impression management by which actors can elicit positive responses from others (Jones 1964). One taxonomy of self-presentation strategies includes ingratiation, intimidation, self-promotion, exemplification, and supplication (Jones and Pittman 1982).

Self-presentation is an important part of social life and is largely a prosocial way that individuals negotiate social interactions. Yet, for the individual, the process of self-presentation may be fraught with tension. These tensions were presented in Goffman’s pioneering work, which provided a sensitive account of internal tensions that can arise in the trade-offs between the need for social approval and the desire for authenticity. Arlie Russell Hochschild’s The Managed Heart (1983) focuses on the emotional work involved in self-presentation. Other scholars (e.g., Erickson and Wharton 1997) have also addressed the conflicts that can arise in self-presentation. Not all individuals attempt or are willing to portray an inaccurate image to their audiences. For some people, psychological needs other than the need for social approval drive behavior.

Self-presentation is complex: It is both an individual difference variable and a function of social situations. Self-presentation strategies differ across individuals but also are influenced by environmental factors. In addition to self-presentation differences observed according to age, gender, and culture, researchers have observed differences in self-presentation based on environmental factors. That is, individuals may elect to alter their self-presentations in response to cues from the social environment. As used here, cues refer to both environmental cues such as the social context (i.e., how public the setting is) and interpersonal cues such as the perceived responses of others. Individuals may also differ in the extent to which they engage in self-monitoring. Self-monitoring is the extent to which individuals monitor their behavior and self-presentation in response to real or perceived interactional cues.

Self-presentation is both an individual experience and a social phenomenon and highlights the tensions inherent in human interaction.

SELF-REPORT METHOD

Social scientists use many methods to collect data. The most common method is self-report, in which people respond to questions about themselves regarding a wide variety of issues such as personality traits, moods, thoughts, attitudes, preferences, and behaviors. In fact, much of social science knowledge and theory are based largely on self-report data.

ADVANTAGES OF SELF-REPORT

The main advantage of self-report is that it is a relatively simple way to collect data from many people quickly and at low cost. A second advantage is that self-report data can be collected in various ways to suit the researcher’s needs. Questionnaires can be completed in groups or individually and can be mailed to respondents or made available on the Internet. Self-report data can also be collected in an interview format, either in person or over the telephone. Researchers can thus obtain data from respondents across a large geographic area or to whom they do not have direct access.
Furthermore, researchers can collect data regarding behaviors that cannot be observed directly or are unethical to simulate in the laboratory (i.e., activities typically done in private and behaviors that would cause embarrassment if done in public). The only person with direct access to mental events and some behaviors is the self; therefore, the self is the best person to report on these variables. Also, respondents completing pencil-and-paper questionnaires with the assurance of confidentiality and anonymity might be more willing to accurately report on a variety of behaviors and characteristics.

**DISADVANTAGES OF SELF-REPORT AND POSSIBLE SOLUTIONS**

There are several disadvantages of self-report that threaten the reliability and validity of measurement. Researchers must ensure that measures are reliable—meaning the outcomes of measurements are repeatable—and valid—meaning the intended variable is measured.

Some threats to validity derive from the way the measure is designed, such as using ambiguous words or words that are not appropriate for the reading level of the respondents. This is especially problematic when different groups (e.g., men and women, adolescents and adults) are likely to interpret words differently or have different reading levels. Researchers must choose words carefully to convey their desired meaning precisely and at an appropriate reading level. Another way to ensure consistent interpretation of items is to provide respondents with a reference group. For example, respondents may be instructed to indicate their level of shyness in relation to people of their same age and gender. It may also be important to provide additional information to ensure that respondents interpret and use response scales correctly, such as providing examples of portion sizes when asking questions about eating habits.

The order of items may also influence how a person responds. For example, people may report different levels of happiness depending on whether they answer this question before or after reporting how many dates they had last month. Researchers should consider how questions might influence answers to subsequent questions. Furthermore, when asking about controversial or potentially embarrassing information, researchers might plan to ask less controversial questions first so that respondents feel comfortable at the outset and thus will be more likely to provide honest responses to more difficult questions.

Other threats to the validity of self-report are due to respondent characteristics. One such well-known threat is socially desirable responding, or the attempt by respondents to make themselves look good. Researchers avoid this problem by using neutral items; by using the Q-sort method of response, in which the respondents are allowed to rate only a certain number of items as highly descriptive of themselves; and by informing respondents that answers are anonymous and/or confidential, thereby encouraging honest responding. Finally, researchers may choose not to use data from respondents who score high on measures of social desirability.

Respondents may have other biases unrelated to item content. They might tend to embrace or avoid extreme responses, or they might exhibit acquiescence, a tendency to agree with statements. These threats can be reduced by requiring respondents to choose one answer from a list. To reduce acquiescence bias, researchers can use measures with items keyed in different directions so that agreeing with some items lowers the total score.

An especially harmful threat to self-report occurs when respondents are intentionally dishonest. Dishonest responding can be decreased by ensuring confidentiality (and anonymity, if possible). Data from people who score high on measures of lying or faking (in both negative and positive directions) can also be excluded from further analyses.

Experimenters may pose threats to the validity of self-report by unintentionally influencing how people respond to questions, which is especially likely with an interview format. Typically, this threat results from experimenters expecting people to respond in line with hypotheses. To lessen this threat, experimenters and interviewers should be unaware of the research hypotheses, and several interviewers should be used to reduce systematic influences of any one interviewer.

The situation and location of interviews may also influence self-report measures. For example, people interviewed on college campuses may agree with the statement “The government should give more money to education” in greater numbers than people interviewed in a park. The situation may serve as a cue to the respondents about the desirable answer, and they may respond accordingly. Even when the respondent is not consciously aware of contextual cues, he or she may still be influenced by them on a subconscious level.

A final threat to validity can occur if all data have been collected with self-report because this is likely to artificially inflate correlations; this problem is known as method variance. In fact, collecting data with any single method has its pitfalls. Researchers who use a single method for collecting data need to be aware of method variance so they can correctly interpret the magnitudes of the correlations found between various measures.

**METHODS OTHER THAN SELF-REPORT**

Multiple methods can be used to gain a multifaceted understanding of variables of interest and to determine
consistency between self-reports and other measurements. Other-report (asking another person about the person of interest) is increasingly being used to examine variables that were previously primarily measured with self-report. Behavioral observation is another method for gathering information about variables commonly assessed with self-report, although this method is more time-consuming and expensive than self-report. To check for accuracy, self-reports can be compared with archival data (e.g., criminal records).

Researchers must keep in mind the purpose of their research to determine which method(s) of data collection to use. If researchers are interested in people's subjective experience of their own thoughts and behaviors, then self-report is appropriate. However, if researchers are interested in more than people's subjective experience of themselves, then a multimethod approach should be used to ensure reliable and valid measurement. Social science researchers are often concerned with more than subjective experience and are beginning to embrace multimethod approaches to data collection. This shift in data collection methods is likely to increase the quality of data available to test and revise social science theories.

SELF-REPRESENTATION

How people define themselves in relation to others greatly influences how they think, feel, and behave, and is ultimately related to the construct of identity. Self-development is a continuous process throughout the lifespan; one’s sense of self may change, at least somewhat, throughout one’s life. Self-representation has important implications for socio-emotional functioning throughout the lifespan.

Philosopher and psychologist William James (1842–1910) was one of the first to postulate a theory of the self in The Principles of Psychology. James described two aspects of the self that he termed the “I Self” and “Me Self.” The I Self reflects what people see or perceive themselves doing in the physical world (e.g., recognizing that one is walking, eating, writing), whereas the Me Self is a more subjective and psychological phenomenon, referring to individuals’ reflections about themselves (e.g., characterizing oneself as athletic, smart, cooperative). Other terms such as self-view, self-image, self-schema, and self-concept are also used to describe the self-referent thoughts characteristic of the Me Self. James further distinguished three components of the Me Self. These include: (1) the material self (e.g., tangible objects or possessions we collect for ourselves); (2) the social self (e.g., how we interact and portray ourselves within different groups, situations, or persons); and (3) the spiritual self (e.g., internal dispositions).

In the late twentieth century, researchers began to argue that the self is a cognitive and social construction. Cognitive perspectives suggest that one’s self-representation affects how one thinks about and gives meaning to experiences. Like James, psychologist Ulric Neisser distinguished between one’s self-representation connected to directly perceived experiences and that resulting from reflection on one’s experiences. The “ecological self,” connections of oneself to experiences in the physical environment, and the “interpersonal self,” connections of oneself to others through verbal or nonverbal communication, comprise direct perception of experience. Neisser proposed that these two types of self-representation develop early in infancy. Regarding reflections on one’s experiences, Neisser identified three types of self-representation that emerge in later infancy and childhood with cognitive and social maturation. The temporally “extended self” is based on memories of one’s past experiences and expectations for the future. The “private self” emerges with the understanding that one’s experiences are not directly perceived by others, but rather must be communicated to be shared. The “conceptual self,” one’s overarching theory or schema about oneself based on one’s reflection on experiences within social and cultural context, parallels terms such as self-concept and self-schema. In a 1977 article, psychologist Hazel Markus showed that one’s self-representation or self-schema guides information processing and influences one’s behavior.

As psychologist Roy Baumeister pointed out in Identity: Cultural Change and the Struggle for Self, because self-representation develops through one’s experience of
the world, cultural and social factors are important in who we are and what we think about ourselves. Philosopher George Herbert Mead (in *Mind, Self, and Society*) postulated that acquisition of self-representation emerges from socialization practices. Mead argued that individuals are socialized to adopt the values, standards, and norms of society through their ability to perceive what others and society would like them to be. Psychologists Tory Higgins, Ruth Klein, and Timothy Strauman further suggested that self-representation includes ideas about who we are (actual self), who we potentially could be (ideal self), and who we should be (ought self), both from one's own perspective and from one's perception of valued others' perspectives. Discrepancies between the actual self and the ideal self or ought self may result in depression or anxiety, respectively.

Attachment theory likewise demonstrates how the self is socially constructed and, in turn, affects how people evaluate themselves (i.e., their self-esteem). Thus, relationships with others play an important role in people's self-representation and self-esteem. Psychologist John Bowlby focused on caregiver-child relationships. Securely attached children feel safe in the environment and are able to actively explore their surroundings. Through experiencing secure attachment to a consistent caregiver, children develop a belief that they are good and worthy of love. This forms the basis of self-esteem. In contrast, an insecure attachment, in which the child does not feel confident in the caregiver's protection, may result in feeling unworthy of love, anxious and distressed, and relatively low self-esteem.

The beginnings of self-representation emerge early in infancy, with the recognition that one is a separate physical being from others. Self-representation development continues throughout adulthood. Because self-representation involves social and cognitive constructions, changes in self-representation occur with individuals' cognitive and social development. Psychologist Susan Harter has conducted highly influential research on the developmental course of self-representation. Excerpts from Harter's summary of self-representation development from early childhood through adolescence (Harter, 1988) are presented in the Table 1.

In addition to cognitive and social maturation, changes in one's social context may be equally important influences on self-representation. For example, Susan Cross (in “Self-construals, Coping, and Stress in Cross-cultural Adaptation”) notes that cultural values influence self-development. As an individual moves from one cultural context (e.g., Eastern culture) to another (e.g., Western culture), changes in self-representation may emerge. Individuals can learn to adopt a self-representation that embraces multiple cultures.

SELF-SCHEMATA

Psychologists have spent a great amount of time and energy studying the self-concept, or how individuals construe themselves. In research on the self-concept, the construct of self-schemata was introduced by psychologist Hazel Markus (1977). Self-schemata are cognitive representations of the self that have implications for information processing and self-regulation.

Schema are blocks of knowledge that help individuals categorize, organize, and process information. Markus built on this idea by suggesting that individuals possess schemas about themselves. These blocks of self-knowledge were coined self-schemata, or self-schema. Self-schemata correspond to characteristics or traits that individuals might use to describe themselves. They may also correspond to the social roles individuals would describe themselves as possessing. Taken together, self-schemata describe an individual’s self-concept.

Markus and Paula Nurius (1986) expanded on the idea of self-schemata from the present to the future. These possible selves, or representations of who individuals might become in the future, are considered to be an extension of the self-concept. Future self-schemata may be positive (hoped-for selves) or negative (feared selves). Possible selves provide an evaluative context for current behavior. Additionally, they provide motivational directions for behaviors in the future by clarifying specific desired or undesired end states.

A frequent method of measuring self-schemata is to record the response speed of individuals as they respond to characteristics presented on a computer screen. Individuals are asked to hit buttons that correspond to the phrases “me” or “not me.” The more quickly an individual is able to respond to an idea, whether the response is positive or negative, the more schematic that individual is in that domain. An alternative way of measuring schemacity is to have individuals list characteristics they view as relevant to their self-concept. The former methodology has the advantage of reducing the influence of social desirability.

John Kihlstrom and colleagues (1988) show that individuals who are schematic are more likely to notice information relevant to that schema and more likely to perceive their own and others’ behavior as relating to that schema. Further research by Ann Ruvolo and Markus (1992) shows that both self-schemata and possible selves are associated with increased memory. This research is consistent with the self-referent effect, the tendency of individuals to more easily remember information that is relevant to themselves. The explanation for these effects is that schema relating to the self are highly accessible.

Research on possible selves suggests that future-oriented self-schemata are related to self-regulation. When possible-self standards are salient for individuals, they are more likely to behave in ways that help them approach hoped-for selves and avoid feared selves. Markus and Daphna Oyserman (1990) extended possible-selves theory by showing that self-regulation is most successful for individuals who possess both a salient hoped-for and salient feared self in the same domain.

SELF-SERVING BIAS

A self-serving bias is any cognitive or perceptual process that is distorted by the need to maintain and enhance self-esteem. When individuals reject the validity of negative feedback, focus on their strengths and achievements but overlook their faults and failures, or take more responsibility for their group's work than they give to other members, they are protecting the ego from threat and injury. These cognitive and perceptual tendencies perpetuate illusions and error, but they also serve the self's need for esteem.

Self-serving biases are particularly evident when individuals formulate attributions about the causes of personal actions, events, and outcomes. When explaining positive actions and experiences, their attributions emphasize the causal impact of internal, dispositional causes, but when identifying the causes of negative events, they stress external, situational factors. The boy who believes his skillful play earned him his victory, the employee who blames her troubles at work on the boss rather than herself, the student who attributes a poor grade to bad luck or the difficulty of the test, and the A student who traces the grade back to hard work and innate ability are all displaying this self-serving attributional bias. Because failure undermines self-confidence and self-worth, individuals seek an external factor that can be blamed for the failure. When they succeed, however, they can bolster their self-esteem by attributing this positive outcome to personal factors (Weiner 1985).

Some people are less susceptible to this bias than are others. Individuals who are depressed or who suffer from chronically low self-esteem tend to take the blame for their failures but deny responsibility for their successes. People in many non-Western cultures also frequently attribute outcomes that lead to negative consequences to themselves rather than external factors. Individuals with an external locus of control consider both positive and negative outcomes to be caused by factors beyond their control, and those with an internal locus of control assume that they, personally, are responsible for their outcomes (Rotter 1966). Overall, however, the tendency to externalize failure and internalize success occurs in a wide range of educational, athletic, and interpersonal situations. Researchers have also isolated the effects of performance feedback on attributions experimentally by giving research participants false positive or negative feedback about their work on a laboratory task. Invariably, those told they failed attribute performance to such external factors as bad luck, task difficulty, or the interference of others, and those told they succeeded point to the causal significance of such internal factors as ability and effort.

Researchers now recognize that a number of cognitive, motivational, and psychological factors combine to create the tendency to internalize success and externalize failure. As Dale T. Miller and Michael Ross (1975) suggest, individuals internalize success and externalize failure because they are usually optimistic when predicting their outcomes and experiences. They expect to pass tests, get good jobs, and have long-lasting relationships rather than fail, get fired, or divorce. Because negative experiences are unexpected, people tend to attribute them to external factors rather than stable, personal ones. Miller and Ross thus conclude that these biases do not always “serve the self,” but are in some cases produced by “cold,” cognitive processes as well as “hot” motivations and needs.

BIBLIOGRAPHY

stellation of self-referent thoughts, feelings, and motives that constitute the individual’s experience of himself or herself in relation to the world. These descriptions range from intrapsychic to cultural in focus, and the accounts of structure and functions range from those that portray the self as a stable, monolithic entity, to those that outline a complex, dynamic system of interrelated elements and processes. These latter accounts typically refer to the self as the self-system.

System-oriented accounts of the self comprise two features: (1) They specify a set of self-aspects—constituents of a differentiated but unified whole; and (2) they posit mechanisms that give rise to the different self-aspects, the interplay between them, and the interplay between the self-system and the experienced world. System accounts often trace their origin to the work of philosopher/psychologist William James (1842–1910), who, in his oft-quoted Principles of Psychology (1890), first described the self as a differentiated entity. James specified two dimensions of differentiation. One is distinctly social, describing self-aspects as internalized representations of the self in relation to significant others. The other dimension positions these representations in the social self, which, along with the material self and the spiritual self, constitute the full self-system.

Although many models of the self-system draw on James’s description, it does not fully describe the self in system terms because it does not posit mechanisms by which the social, material, and spiritual selves arise, and it does not offer a systematic account of the interplay between these self-aspects or between the self-system and the experienced world. In perhaps the earliest fully drawn model of the self-system, Harry Stack Sullivan (1892–1949), in The Interpersonal Theory of Psychiatry (1953), outlined the interpersonal processes that give rise to the self-system. The good-me arises from positive interactions between the infant and caregiver. The bad-me arises from interactions with the caregiver that engender anxiety. Finally, the not-me encompasses interpersonal aspects of the self-system that are nonconscious—the “private mode of living.” These self-aspects are a joint product of interrelated elements and guard against anxiety in interpersonal relations.

The cognitive revolution of the 1960s provided social scientists with the conceptual and methodological tools for developing and studying models that proffer more detailed accounts of the structure of the self-system and richer accounts of processes that operate within the self-system and between the self-system and the environment. In terms of structure, these models generally view the self-system as a highly organized network of knowledge structures that are either activated directly through self-directed attention or by stimuli in the environment or indirectly as a result of their association with other knowledge structures that have been activated. Once activated, these constituents of self-knowledge influence attention, perception, emotion, and behavior, typically, in a manner that ensures the stability and continuity of the self-system across situations and over time.

SELF-VERIFICATION

Self-verification theory proposes that people want others to see them as they see themselves. For example, those who see themselves as relatively dominant want others to see them as dominant, and those who see themselves as relatively submissive want others to recognize them as submissive. The theory was developed by William B. Swann Jr. (1983). Drawing on earlier theorizing, he assumed that people form self-views so that they can predict the responses of others and know how to act toward them. Thus, for example, those who see themselves as intelligent expect that others will notice their insightfulness and so are inclined to pursue activities that require intelligence. Because self-views play a critical role in making sense of their experiences and guiding their actions, people become invested in maintaining them by obtaining self-confirming information.

Among persons with positive self-views, the desire for self-verification complements another important motive, the desire for self-enhancing or positive evaluations. For example, those who view themselves as “organized” find that their desires for both self-verification and self-enhancement compel them to seek feedback that confirms their positive, “organized” self-view. People with negative self-views, however, find that the two motives conflict: Although the desire for self-verification compels such persons to seek negative evaluations, the desire for self-enhancement compels them to seek positive evaluations. Self-verification theory points to the conditions under
which people with negative self-views resolve this conflict by seeking self-verification rather than self-enhancement.

Considerable evidence supports self-verification theory (Swann 1996). In one study, researchers asked participants with positive and negative self-views whether they would prefer to interact with evaluators who had favorable or unfavorable impressions of them. Those with positive self-views preferred favorable partners, but contrary to self-enhancement theory, those with negative self-views preferred unfavorable partners.

Many replications of this effect using diverse methodologies have confirmed that people prefer self-verifying evaluations and interaction partners. For example, not only do self-verification strivings influence the relationships people enter initially, they also influence whether or not people remain in certain relationships. Research on married couples, college roommates, and dating partners show that people gravitate toward partners who provide verification and drift away from those who do not—even if this means withdrawing from positive partners. And even if people wind up with partners who do not see them in a self-verifying manner, they may correct the situation by changing their partners’ minds. College students who were mildly depressed, for instance, were especially likely to solicit negative evaluations from their roommates, and such activities made their roommates more inclined to derogate and reject them at the semester’s end. And even if people should somehow fail to elicit self-confirming evaluations, information-processing biases in attention, memory, and interpretation may make their social works appear to be more confirming than they actually are, thus stabilizing their self-views.

Self-verification strivings are adaptive for most people because most people have positive self-views, and self-verification processes enable them to preserve these positive self-views. Also, within small groups, verification of negative as well as positive self-views may also facilitate commitment and performance. Yet for people with negative self-views, self-verification strivings may have undesirable consequences, causing them to gravitate toward partners who undermine their feelings of self-worth.

The major criticism of self-verification theory has been that, relative to self-enhancement, it is a rare phenomenon that is restricted to people with terribly negative self-views. As evidence, critics cite hundreds of studies indicating that people prefer, seek, and value positive evaluations more than negative ones. Such critiques overlook two important things. First, because most people have relatively positive self-views, the fact that they display a preference for positive evaluations may reflect a preference for evaluations that are self-verifying (as well as self-enhancing). Second, self-verification strivings are not limited to people with globally negative self-views; even people with high self-esteem seek negative evaluations about their flaws, and even people with moderately positive self-views withdraw from spouses who evaluate them in an exceptionally positive manner.

SELIGMAN, MARTIN 1942–

Born in 1942 Martin E. P. Seligman is a noted psychologist whose contributions to psychological science include a better understanding of depression and the stimulation of interest in the positive aspects of personal growth and development. He earned his bachelor’s degree summa cum laude in philosophy at Princeton University in 1964 and his doctor of philosophy in experimental psychology at the University of Pennsylvania in 1967.

In his early work Seligman focused on animal models of learned helplessness. Among his discoveries he found that when dogs were subjected to inescapable shocks, they later failed to attempt escape or to avoid such shocks, at least temporarily. His research also demonstrated that the learned helplessness could be reduced with appropriate training. According to Seligman and his fellow researchers, the animals had learned that their attempts at escape behaviors were not rewarded, so those attempts were extinguished.

Subsequently psychologists extended his work with the animal model to include discussion of such behavior in people. Psychologists addressed the question of why people sometimes fail to escape from untenable situations when escape is possible. As psychology, as a discipline, moved from behavioral to cognitive explanations of behavior, researchers focused less on reinforcement contingencies and more on thought processes, such as the
expectation with learned helplessness that one could not control one's environment, so action would be futile.

Subsequent to his investigation of learned helplessness and its connections to depression, Seligman began focusing on coping and adaptation, developing the emerging field called positive psychology. This approach has at its heart the idea that people are motivated to thrive; it concerns itself with healthful approaches to life by individuals and by institutions. Positive psychology focuses on understanding (1) positive emotions like contentment with the past and hope for the future; (2) positive individual traits like the capacity for work and love, curiosity, integrity, and self-control; and (3) positive institutions that foster the creation of justice, civility, and tolerance (Positive Psychology Center 2007).

To promote positive psychology Seligman created the Positive Psychology Center at the University of Pennsylvania. The center is designed to promote research and dissemination of positive psychology. The domain has generated research programs and innovative ideas; at the same time, another of Seligman's goals is to foster societal action that promotes psychological growth within communities. The combination of theoretical, empirical, and applied ideas led in 2006 to the creation of the Journal of Positive Psychology.

Seligman has been recognized for his contributions in numerous ways. In 1998 he was elected the president of the American Psychological Association (APA), the largest organization of psychologists in the world. Prior to that he served as president of Division 12 (Clinical Psychology) of the APA. In addition he has been elected fellow of seven APA divisions: General Psychology, Experimental Psychology, Behavioral Neuroscience and Comparative Psychology, Society of Clinical Psychology, Adult Development and Aging, Health Psychology, and International Psychology. Seligman is also a fellow of the Association for Psychological Science, the Behaviour Research and Therapy Society, and the Pennsylvania Psychological Association.

He has received fellow status in nonpsychological organizations as well, including the American Association for the Advancemnt of Science and the Society of Behavioral Medicine. He has garnered honorary doctorates from Uppsal University in Sweden, Massachusetts College of Professional Psychology, and Complutense University in Madrid.

SELLING LONG AND SELLING SHORT

In the field of finance selling long (or going long) on a security or an investment means that an investor buys that security or investment with the prospect of keeping it for some time because he or she believes that its price (or value) is going to increase in the long run. This investment action is called a long position in that particular security or investment.

The opposite practice is known as selling short or short selling a security or investment. An investor who gets involved in short selling believes that the price of the underlying security is going to decrease in the near future. Hence, that investor borrows shares of the security he or she anticipates will have a price decrease and then sells those shares at the current market price, expecting to pay back the loan in stocks when the price of the security drops. This way the investor makes a profit by selling high and buying low, but he or she sells first and buys later. Thus, because the investor does not own the underlying security but only borrows and sells it, it is considered that that investor is in a short position regarding that particular security. Of course, a high risk is involved in such investment actions because the price of the security or investment in which someone has a short position could rise instead of fall, and then the investor has to pay more and loses money instead of gaining as he or she anticipated.
In general, an investor will go long or have a long position in a security or an investment when that investor expects the price to rise and will have a short position when he or she expects the price to drop. However, short selling is not allowed in all countries. The term short is used because it indicates an inadequacy, and in finance it is applied to situations in which investors sell securities that they do not own. Therefore, such a sale is called short sale because it creates an inadequacy, a negative position, in the sold security. In a portfolio the percentage that shows the portion of the security that is in a short position is negative. The securities in which a long position is held have positive percentages in portfolio weights. The sum of the portion of each security that makes up a portfolio is always equal to one despite any long or short positions in the participating securities.

SHORT SELLING IN THE UNITED STATES

In the United States the process of short selling proceeds as follows:

1. An investor interested in short selling borrows shares of a security from a brokerage firm. However, in the United States there is a rule that the investor has to deposit cash in his or her brokerage firm amounting to 50 percent of the value of the borrowed shares (this is called a margin).

2. The investor then sells the borrowed shares and credits the proceeds from the sale at his or her cash account in the brokerage firm.

3. At a specified time agreed on with the brokerage firm the investor must close the position by buying back the shares from the market.

4. The investor must return the shares to the broker (lender) as was agreed. If the price of the underlying shares increases, the investor suffers a loss. If that price decreases as expected, the investor makes a profit.

Furthermore, by law since 2005 regulated broker-dealers in the United States do not allow their customers to short sell securities if the customers have not arranged for a broker-dealer to confirm that the brokerage firm is able to deliver the underlying securities. This process is called locating. The brokerage firms can borrow shares in many ways, facilitating locates and delivering the short-selling securities. U.S. brokers can borrow stocks from leading custody banks such as JP Morgan Chase (New York), Citibank (New York), Mellon Bank Corp. (Pittsburgh), the Bank of New York (New York), the Northern Trust Company (Chicago), State Street Corporation (Boston), Robeco (Netherlands), UBS (Zurich), fund management companies, and even their customers who have long positions in those stocks.

In the United States, to avoid a high amount of loss, short sellers can place a stop loss order with the brokerage firm after selling a stock short. Then the broker has to cover the position if the price of the underlying stock increases to a certain level, limiting the loss to the customer.

A short-selling investor has to pay a fee at the brokerage company that facilitates that investor's short-selling activities. Usually this is a standard commission fee, as with buying a security.

If the price of the shares in a short position rises instead of falling, the broker will deduct money from the investor's cash account and transfer it to the investor's margin account. If the price continues to increase and there are not enough funds in the investor's cash account to cover the investor's position, the investor will have to borrow on margin and will begin to accrue margin interest charges. Furthermore, if the stock on a short position pays dividends and the dividend date passes while the investor is short on the stock, the dividend will be deducted from the investor's account.

THE BENEFITS AND HISTORY OF SHORT SELLING

According to Jones and Lamont (2001), short selling makes an important contribution to the efficiency of the stock market. There are limits to arbitrage. Specifically, some stocks can become overpriced. A group of investors may realize this and adopt a short position in those overpriced stocks. When the stocks are sold in the market, their prices are driven downward (high supply, low prices), and eventually they reach an equilibrium price level.

Historically, short-selling practices were reported in the seventeenth century during the scandal that arose after the violent fall of the Dutch tulip market. In the eighteenth century England banned short selling. In the nineteenth century the term short was used in the United States. In the early twentieth century the short-selling activities of traders were blamed for the Wall Street crash of 1929. After that time severe regulations on short selling were implemented in 1929, 1938, and 1940. Legislated rules that banned mutual funds from engaging in such activities were lifted in 1997. In 2005 the Securities and Exchange Commission established locate and close-out requirements for brokerage firms.

SELLOUTS
The label sellout has referents in cultural, social, political, and economic communities. In idiomatic use, sellouts are people affiliated with a person or group (who typically have subordinate social status) who are perceived to have betrayed that person or group, their interests, and/or an ideology or cause. To sell out is to betray a group and/or cause.

Sellouts are often accused of betraying groups to which they had belonged previously, and which have a subordinate status to the group in power. These groups might be family, kin, or friendship-based groups, or larger, socially constructed or imagined communities based on nationality, race, gender, sexual orientation, or class. Or the groups might be collectives, such as musicians of a marginalized style of music, environmentalists, members of business conglomerates, or international business partnerships seeking to maximize national profits in a competitive global economy.

These groups often have a specific ideological orientation that requires solidarity or a cause, and sellouts are said to be traitors to the cause. The sellout’s attempt to benefit himself socially, culturally, politically, or economically has negative implications for the subordinate group and a positive effect for the group in power—often referred to as the mainstream.

In their work on the economics of identity, William Darity, Patrick Mason, and James Stewart (2006) imply that there is an underlying relationship of domination and subordination between groups (in their work, racial groups) that leads to conflicts and the creation of alternative social norms. Darity et al. contend that the incentives for conflict relate to inequalities in material resources persistent in a society such as the United States with a racialized economic equilibrium that favors whites over other racial groups. This results in racialized individuals and racialized groups pursuing either a racialist or an individualist identity strategy.

A racialist identity strategy permits access to intragroup altruism while identifying individuals for outgroup antagonism—that is, minorities versus whites and vice versa. People working under this system have strong loyalties to their racial group and the causes of the collective membership, especially members of the oppressed racial group. Thus, sellouts are individuals from the subordinate group who reject the racialist identity strategy in favor of an individualist strategy, opting for alternative social norms for personal gain rather than for the norms and practices of racialist altruism. The sellout’s actions often hinder the collective racial advancement toward the group cause.

In Latina/o communities in the United States, vendidola (“sellout”), Tío Taco (“Uncle Taco”), and “coconut” (“brown on the outside and white on the inside”) are often used as derogatory labels for sellouts who betray their loyalties to the Latina/o group or their cause against white domination. Similarly, in Asian American communities a “banana” is a person who is said to be “yellow on the outside and white on the inside,” and in American Indian communities, an “apple” is “red on the outside and white on the inside.” The most articulate definition of the concept and label in the African American community is documented by Geneva Smitherman, who defines a sellout as “an African American who isn’t DOWN WITH the Black cause, one who betrays the race and compromises the COMMUNITY’S principles, usually for personal gain…. By extension, anyone who GOES FOR SELF and abandons his or her group’s collective mission” (Smitherman 2000, p. 200). Other referents to sellouts in the African American community include “passing” (for white) and the labels “Oreo” (the cookie, “black on the outside and white on the inside”) and “Uncle Tom” (from the 1851–1852 Harriet Beecher Stowe novel Uncle Tom’s Cabin). Studies on this topic in the field of education were originally framed under the concept of “acting white” (Fordham and Ogbu, 1986).

Assimilation and acculturation are forms of selling out on a large scale through dissociating from the cultural,
gender, class, racial, or sexual orientation norms and practices of subordinate group membership.

Besides gaining access to resources denied the subordinate group, sellouts may have a more altruistic motivation, such as a desire to work within the system for change; nevertheless, they may be accused of selling out. Others may be motivated to sell out for personal security—that is, to avoid physical and or ideological persecution by the oppressing group. Sometimes sellouts are co-opted by the dominant group to promote their agenda, then “disposed of” without receiving the expected benefits. Or they may feel guilty for abandoning their original (subordinate) group and never achieve full acceptance by the dominant group.

Luis Urrieta Jr.’s work with Chicana/o activist educators (2005) highlights the complexity of the issue of selling out, illustrating that there is more of a gray area than the “either/or” dichotomy allows. The tipping point of when people are in danger of becoming sellouts is rather arbitrary, and selling out is idiomatically understood differently in various communities, thus eluding a standardized definition.

Semantic Memory

In 1972 the cognitive scientist Endel Tulving (b. 1927) argued that conscious recollection (i.e., declarative memory) is composed of two separate memory domains, each having distinct functionality, knowledge access, and neurological localization. Whereas episodic memory involves our conscious recall of past events within some specific context, semantic memory involves our recall of factual knowledge that is not context-dependent.

Psychologists have assessed semantic memory through a large array of tests. For example, in recalling a previously studied list of words, participants often recall groups of words in sequence (i.e., cluster) on the basis of thematic or taxonomic relations, even though the words were ordered randomly at presentation. Measures of the time required to make various forms of judgments also reflect semantic memory structure. Variation in the time required to name visually presented words, or to discriminate words from nonwords (lexical decision), reflects access to semantic information about words. Similarly, the time required to make category judgments, such as whether a robin is a bird, can be used to infer some properties of semantic memory structure.

Analyses of lexical access and category judgment tasks have led to the development of network models, which describe how the components of semantic information (e.g., concepts) are organized within semantic memory. In a hierarchical network model, for example, access to each lower-level item depends on the higher-order category (e.g., robin–bird). In contrast, other models propose that semantic memory is not organized hierarchically, though information is related to varying degrees. In these latter models, memory retrieval occurs in parallel, as a result of the activation of related information within the network. Recently, connectionist models have furthered this notion and have depicted semantic memory networks as highly distributed yet unitary systems whose multiple elements work largely in parallel.

The network and connectionist models are based on accounts of behavioral data and mathematical simulation. The question of how semantic and episodic memory abilities are represented in the brain is currently controversial. Studies of neurological patients suggest that damage to medial temporal regions of the brain can impair episodic memory while leaving semantic memory largely intact. Neuroimaging studies of healthy individuals also indicate some degree of differentiation in the pattern of brain activation occurring during episodic and semantic memory tasks, but there is also a substantial degree of overlap. Though details vary according to task demands, neuroimaging research suggests that left prefrontal regions, medial temporal regions, ventral visual processing areas, the hippocampal formation, and parts of parietal cortex can all play a role in semantic memory processing. Accessing semantic information, however, can also be a form of episodic encoding. That is, the best way to prepare for a later episodic test is to encode the meaning of the information to be remembered (as opposed to its physical structure). Typically, the left prefrontal region of the brain is implicated in both semantic retrieval and
episodic encoding, and the right prefrontal region is implicated in episodic memory retrieval. This complex network of cortical involvement reflects the growing recognition among researchers that semantic memory comprises several component processes.

**SEMIOTICS**

Toward the end of the seventeenth century John Locke (1632–1704) partly hoped for, partly prophesied, and partly proposed a new field of inquiry called “semeiotike.” That “doctrine of signs,” which he characterized as “aptly enough also, logic,” invites the reader to “consider the nature of signs, the mind makes use of for the understanding of things, or conveying knowledge to others” (Locke [1690] 1996, p. 337). Locke’s proposal was neglected until the American logician-philosopher-mathematician Charles Sanders Peirce (1839–1914) picked up its charge in his writings from 1866 until his death in 1914. In keeping with what he considered the “ethics of terminology,” Peirce named this effort, which he describes as “the doctrine of the essential nature and fundamental varieties of” possible sign-activity, *semeiotic* (emphasizing the diphthong *ei* in *semeion* [sign] in its spelling to indicate the word’s Greek origin), though he sometimes used the term *semitic*.

Independently of Peirce and Locke, the Swiss linguist Ferdinand de Saussure (1857–1913) determined to study the “life of signs in social life” and named his “new” science *semiology*. In contrast to Peirce’s writings, his lecture notes, which were compiled and published posthumously in 1966 by his students as *Cours de Linguistic Générale*, caught the attention of several leading linguists and “signophiles” soon after his death.

**NOMENCLATURE**

In addition to *semiology*, *semitic*, and *semitic*, there were also available the labels, *semiotics*, *significs*, and *signology*. However, the struggle for recognition was between *semiology* and *semitics*, and *semitics* won the day. Apart from the deliberate extension of their inquiries into extralinguistic sign systems and their choice of a label to describe their work, most self-styled semioticians were semioticians by another name and the *Cours* remained their foundational text. Among the rest, *semitic* and *semitic* were to become associated with those whose research followed more or less Peircean lines. Nevertheless, there have been considerable crossovers in the use of labels and some mixing up of theoretical orientations as well. Many Peirceans use *semitics* and non-Peirceans use *semitic*, though the latter employ it mostly as an adjective rather than as a noun in their writings. *Semiotic* is never used by Saussurians, and Peirceans who use that term do so to mark the difference of their approach to the sign from that of the Saussurians.

**SAUSSURE AND SEMIOLOGY**

A linguistic sign as defined by Saussure is a two-sided phenomenon, a relationship that links an acoustic image and a concept, or a signifier and a signified. The link is not between a thing and its name but between a sound pattern and a concept. That relationship is internal to language, internal to the mind, and independent of external reality. Therefore, a linguistic sign does not “stand for” an external world but construes it. Thus, a tree that is signified by the word *tree* is not an actual tree but the concept “tree.” Similarly, a signifier does not stand for the signified but instead construes it. The signifier and the signified are “functives” that are copresent or co-occurrent, although on different strata, with the first being more abstract than the second. In their respective strata they “exist” in a context of other signifiers and signifieds, respectively. Each is held together with and held apart from the other signifieds and signifiers in their respective strata by similarities and differences; that is what makes them part of a system or structure.

Which signifier pairs with which signified is determined by convention; it is arbitrary from an empirical point of view. The external world is brought into a relationship with the internal structure by the projection of the internal structure on the external world. That logocentric view overly simplifies a being’s living-in-the-world and its engagement with that world to the point of solipsism. The semiologically structured internal relationship of the signifier to the signified analogically structures, organizes, and orients sign users to the flux of percepts they receive from the external world. This is a nominalistic view of both language and the world.
There are many reasons why the semiological model of the sign—dyadic, nonmaterial and confined to a hermetically sealed system called language—came to assume paradigmatic power over semiotics generally. The foremost reason is structural: Only human beings have culture. Not all the features that constitute culture are uniquely human, but language is. What makes human language unique is *la langue*. The linguistic sign is the defining element of *la langue*. The defining feature of the linguistic sign is its binary structure, in which the elements of the dyad are held together by a relationship that is arbitrary or conventional (as opposed to natural). From this it is hypothesized that even though the uniquely human institution called culture is not identical to language, because its only assuredly human feature is language, the elementary form of culture must be structured along the lines of the elementary form of language: the linguistic or semiological sign.

**PEIRCE AND SEMIOTIC**

One can find as many as eighty-eight definitions of the sign in Peirce's published and unpublished writings. Peirce defined and adjusted the definition of the sign to a range of contexts, a short list of which includes mathematics, logic, philosophy, pendulum experiments, chemistry, psychology, language, history, realism-nominalism debates, scholasticism, metaphysics, theories of mind, and discussions of truth. He often bent his definitions for the benefit of his interlocutors and correspondents' comprehension.

Peirce had a pansemiotic view of the world. The sign easily transgressed such dichotomies as mind-body, nature-culture, human-animal, internal-external, and matter-spirit. For Peirce the universe is “perfused with signs.” He considered thought as semeiotic sign activity but “not necessarily connected with a brain. It appears in the work of bees, of crystals, and throughout the purely physical world.” He claimed that “not only is thought in the organic world, but it develops there,” granting that “signs must have a Quasi-mind.” His belief that “there can be no isolated sign” was frustrated by demands for a definition of the sign, for he considered a sign only as part of a semeiotic process (Peirce 1934, vol. 4, para. 551; vol. 5, para. 448).

Peirce held that even “a person is not absolutely an individual” but a state of consciousness. Every state of consciousness was an inference for Peirce, and therefore life itself was a sequence of inferences or a train of thought. “At any instant then man is a thought.” Moreover, if consciousness is taken to mean thought, he reminds the reader that thought “is more without us than within. It is we that are in it, rather than it in any of us.” Here Peirce anticipates Michel Foucault’s idea of episteme and discourse as well as his critique of the overrating of “agency” by modern individualism. Man’s “thoughts are what he is ‘saying to himself,’ that is, saying to the other self that is just coming into life in the flow of time. When one reasons, it is that critical self that one is trying to persuade.” Human “thought,” he opined, was a sign, “mostly of the nature of language.” Given that language is by and large constituted of symbols, and that “at any instant … man is a thought, and … thought is a species of symbol, the general answer to the question what is man? is that he is a symbol” (Peirce 1934, vol. 5, para. 421; 1958, vol. 7, para 583; 1958, vol. 8, para. 256).

**DIFFERENCES BETWEEN SAUSSURE AND PEIRCE**

There are many differences between Saussure’s and Peirce’s concepts of the sign. The Saussurian sign is dyadic, originating in linguistics, whereas the semeiotic sign is irreducibly triadic and based on logic. Also, logic as semeiotic is a normative or formal science, in contrast to the empirical sciences such as linguistics and psychology, which Peirce classified as special sciences. As a formal science, semeiotic is concerned with the necessary conditions for what makes something a sign as such, the bases on which to determine its truth, and the conditions that are required for the communication and growth of signs.

Peirce derived the proof for the sign’s triadicity from logic, mathematics, and phenomenology. With a certain amount of familiarity with a number of his scattered definitions of the semeiotic sign, one can begin to appreciate the complexity of the sign and the work it does. In the triadic sign, the first thing to know is that the first correlate of the triad is the sign (at times called the representamen), the second correlate is the object, and the third is the interpretant. Thus, the semeiotic Sign (uppercase) is constituted by an irreducible triadic correlation in which a sign (lowercase) stands for an object to an interpretant. The sign as the conveyer of meaning mediates between the object and the interpretant; the interpretant mediates between the sign and the object to interpret the meaning; the object mediates between the interpretant and the sign to ground the meaning. If any one of the three correlates is removed, the Sign as such will not be an actual Sign but merely a potential Sign.

Despite his numerous attempts to fix the sign in a definition, Peirce’s fundamental conception of semeiotic was the process of “sign-ing” or semiosy rather than the sign per se. This is evident in the following definition: “The *sign* is anything which determines something else (*its interpretant*) to refer to an object to which itself refers (*its object*) in the same way, the *interpretant* becoming a *sign in turn*, and so on *ad infinitum*” (Peirce 1934, vol. 2, para. 303). When defined in this way, the sign brings out the open and dynamic nature of sign activity or semiosy.
Semiosy is the very life of the sign. When semiosy ceases, the sign either dies or goes into hibernation until an interpretant-sign predisposed to receiving its representation of the object arrives. Thus, a potsherd from an antique goblet would “hibernate” until a knowledgeable archaeologist found it, realized it, and represented it as a sign of an antique goblet to a student. The student would, as the next interpretant-sign along the chain of revivified semeiosis who was fit to receive (by training) the representation, then translate and communicate the meaning of the represented object to yet another interpretant-sign (that student’s own students, say) even as the professor’s representation of the potsherd as representing the original goblet was communicated to the original student. And then the represented object will be represented to someone else, that is, yet another interpretant, ad infinitum. The very structure of the semeiotic sign establishes it as fundamentally and minimally dialogic.

At the most abstract level there are three types of interpretants: the immediate, the dynamic, and the final. Peirce describes the immediate interpretant as the immediate pertinent possible effect in its unanalyzed primitive entirety (Robin 1967). A dynamic interpretant is the actual manifestation of a significant effect. A final interpretant is the teleological growth of a sign that makes its home an interrelated system of signs. The three interpretants that correspond in human experience to these abstract interpretants are the emotional, the energetic, and the logical interpretants. The feeling of déjà vu would be an example of an emotional interpretant; the bodily reaction of a person at whom the command “halt!” is barked out by a soldier after the declaration of a curfew would be an example of an energetic interpretant; the habitualized mode of conditional reasoning such as “if the light turns red, I will not cross the road” would be a logical interpretant. The dynamic interpretant does not possess meaning but is a brute reaction; neither does an emotional interpretant that remains at the level of a mere feeling before being put into words have meaning. A logical interpretant is meaningful. The path a river takes is a final interpretant: a habit carved into the earth. There are many other triadic sets of sign types and other triadic phenomena in Peirce’s writings. They are generated by the logic of Peirce’s phenomenological categories of Firstness, Secondness, and Thirdness; the possible, the actual, and the general, or “mood, the moment, and mind,” respectively (Daniel 1996, pp. 104–134).

SEMIPARAMETRIC ESTIMATION

Econometrics and other statistical sciences deal with the estimation of various functions (models) such as conditional density function, regression function (conditional mean), heteroskedasticity function (conditional variance), and auto-covariance function (conditional covariance). For empirical research, economic theory suggests the types of variables that can be used in these models under consideration, but often it does not provide the functional form of these models. In view of this, empirical and theoretical work in econometrics is usually done by assuming linear or nonlinear parametric functional forms of these models (see Hartley 1961 and Gallant 1987). However, these parametric models may be false and may therefore provide biased and misleading estimates and inferences. In view of this, econometrics moved in the direction of data-based local modeling for studying these econometric models of unknown functional forms. This approach is also called the “nonparametric (NP) method” or “NP smoothing.” There are various NP methods, including spline methods, series methods, differencing methods,
and neural-network methods, but the NP kernel smoothing method has become particularly popular because of its vast applicability, its simplicity, and its well-developed theoretical results. NP kernel methods involve local averaging; for example, a consistent estimate of the regression model is obtained by locally averaging those values of the dependent variable that are “close” in terms of the values taken on by the regressors, and these are determined by a “window width.” The NP kernel estimation procedure was developed in the seminal works of Murray Rosenblatt (1956), Elisbar Nadaraya (1964), and Geoffrey Watson (1964). (See also Fan and Gijbels 1996 and Pagan and Ullah 1999 for a detailed development on this subject.)

A major complication in a purely NP method is the “curse of dimensionality.” The cost associated with using the NP method is the need for very large data, especially when the number of variables in the model is large, if an efficient measurement of the model is to be made. This problem leads to the idea that one might try to restrict some variables, say in a regression model, to have a linear parametric impact while allowing others to have an unknown functional form. As an example, in the female wage model the wage is considered as being linearly affected by the females’ personal characteristics, but the variable, the number of years of job experience, can be of unknown functional form. Effectively, estimation involves a combination of parametric and NP methods, leading to the estimators being described as semiparametric (SP). In general, SP models contain both parametric and NP models, and over the years, a large class of SP models have appeared in the econometrics literature (see Robinson 1988; Linton 1995; and Pagan and Ullah 1999).

Suppose one wanted to estimate the function \( g \) in the regression function

\[
y_i = g(x_i) + u_i, \quad i = 1, \ldots, n
\]

where \( y_i \) is the dependent variable, \( x_i \) is a vector of \( q \) regressors, and \( u_i \) is an additive error. A parametric approach fits the data to a parametric model \( g(x) = g(x, \theta) \), often a linear model with \( g(x, \theta) = \alpha + x\beta \), where \( \theta \) is a parameter set of the model. The least squares estimator \( \hat{\theta} \) is obtained by minimizing

\[
\sum_{i=1}^{n} [y_i - g(x_i, \theta)]^2
\]

over \( \theta \), and this estimator is consistent and asymptotically normally distributed (see Gallant 1987). In the NP estimation method, first the regression function \( g(x) \) is considered as a local polynomial regression, say linear, as \( y_i = \alpha(x_i) + (x_i - x)\beta(x_i) + u_i \) for \( x_i \in x \pm h/2 \). Then the NP local linear regression estimation method leads to the following weighted squared loss minimization

\[
\min \sum_{i=1}^{n} (y_i - \alpha(x) - (x_i - x)\beta(x))^2 K\left( \frac{x_i - x}{h} \right)
\]

where \( K(\cdot) \), a nonnegative weight (kernel) function, is a decreasing function of distances of \( x_i \) from the point \( x \), and \( h \) is a window width that determines how rapidly the weights decrease as the distance of \( x_i \) from \( x \) increases (see Pagan and Ullah 1999).

The SP estimation method deals with the SP models where one component is parametric and the other is NP. A popular SP model is \( g(x, \theta) = x_i\beta + g(x, \gamma) \), where \( x_i \) and \( x_\gamma \) are \( q \) and \( q_\gamma \), \( q = q_1 + q_\gamma \) sets of variables and the model is linear in \( x_i \) but the functional form in \( x_\gamma \) is unknown. The SP estimation of \( \beta \) involves the parametric least squares estimation of \( \beta \) in the regression of \( y_i \) on \( x_i \), where \( y_i = y_i - \hat{E}(y_i|x) \), and \( \hat{E}(x_i|x_\gamma) \) are generated by first estimating the conditional means appearing in them by the NP method. Another SP model arises where \( g(x, \theta) \) is taken to be a known parametric model and where the distribution function of the error \( u \) is known and not assumed to be normal. In this case, the SP estimation of \( \theta \) is done by writing the likelihood function of the model under the density specified by its NP kernel estimator. The efficiency properties of these estimators have been extensively studied (see Robinson 1988; Bickel, Klaassen, Ritov, and Wellner 1992; and Pagan and Ullah 1999). Other SP models’ estimation includes the situations where \( g(x, \theta) = x_i\beta \), but \( V(u|x) = \sigma^2(x) \) or the serial correlation in \( u_i \) is of unknown form. In addition, there is an extensive class of applied SP models with limited dependent variables (see Linton 1995; Horowitz and Lee 2002; and Pagan and Ullah 1999).

Extensive work on the empirical applications of SP models has begun to appear in both cross-section and time-series econometrics, especially in labor econometrics and financial econometrics. Although some related work is being done, several challenging research issues remain. The first is the development of a unified approach toward a data-driven window width and the development of user-friendly software. Others include the systematic development of work on SP estimation of panel-data models, especially when the time-series component is nonstationary, and the development of the theory of SP estimation of models with both continuous and discrete variables (see Racine and Li 2004).

The SP estimation method is a fast-growing area of research in econometrics and statistics. With advances in computer technology the applications of the SP approach are rapidly increasing. In a wide sense, the frontier of this research area has moved on, and it is expected to continue growing in both theory and applications.

Aman Ullah

SEN, AMARTYA KUMAR

1933–

Amartya Kumar Sen was born November 3, 1933, in Santiniketan, India. He is a central figure in modern welfare economics, social choice, and development economics. Equal parts philosopher and economist, Sen is unique among modern economists in insisting on the centrality of values and ethics. His most influential works include theoretical contributions to social choice theory, theories of inequality, and the mechanisms underlying poverty.

Sen’s early arguments questioned the foundational assumptions of the mainstream approach to social welfare analysis. In 1970, two seminal works greatly expanded social choice theory (the study of the aggregation of individual preferences to form a collective choice). In *Collective Choice and Social Welfare*, Sen showed that Arrow’s impossibility theorem (the idea that no voting system meets a desired set of criteria when there are three or more choices) collapses once interpersonal comparisons are allowed. He also established the feasibility of several approaches to constructive social decisions. In “The Impossibility of a Paretian Liberal,” he showed that the critical assumption of paretian optimality (an allocation of resources in which no one can be made better off without making someone else worse off) is not value-neutral, as previously supposed. Instead, it conflicts with other fundamental liberal norms, particularly the importance of liberty in the personal domain. Later, in “Rational Fools” (1977), he contested the narrow behavioral assumption that rationality is interchangeable with self-interest, showing it to be an inadequate characterization of human motivation.

These advances in social choice theory allowed for the construction of several non-paretian criteria for social welfare functions. Sen’s own explorations (with various authors) were in the areas of inequality, poverty, and distribution-adjusted national income measures. In his explorations of distributive justice and poverty, Sen developed the use of entitlement analysis and the capability approach to development. In *Poverty and Famines* (1981), he presented a theory of famine causation that concentrated on a collapse of people’s entitlements (the commodities that different persons can acquire), and he investigated different economic processes that can lead to famines, arguing that they need not necessarily connect with a low or decreasing food supply. He illustrated this theory with detailed case studies of many actual famines, including the Bengal famine of 1943 and the Ethiopian famine of 1973 and 1974.

For Sen, development is seen as the expansion of capabilities and associated human functionings. *Capabilities* are the constituent elements of development, comprising wide-ranging substantive freedoms such as the ability to feed oneself or to participate in economic and political activities. *Functionings* are the actual things humans may wish to do or be. Poverty, therefore, is not simply the deprivation of income, but a deprivation in capabilities.

The growth of additional practical indicators of social welfare and advances in understanding capabilities contributed to alternative methodologies to evaluate development. A direct result of this was the genesis of the United Nations’ *Human Development Report*. Sen has also been at the forefront of incorporating discussion of gender inequalities and the role of women in development. In “Missing Women” (1992), he addressed the role of gender
inequalities in mortality in parts of the developing world. This was supplemented by a 2003 study of the new phenomenon of selective abortion of female fetuses.

Sen has taught in India, the United Kingdom, and the United States, and he is the recipient of numerous awards, including the 1998 Nobel Prize in Economics.

SENeca

The Senecas are an American Indian group from northeastern North America. One of the six nations of the Iroquois Confederacy, or Haudenosaunee, Senecas call themselves Onodowaga, meaning “People of the Great Hill.” Traditional Senecas determine group membership matrilineally (through the mother’s line) and speak a language in the Northern Iroquoian language family. It is likely that several previously autonomous groups coalesced to form the Seneca nation in the fifteenth or sixteenth century, prior to Seneca entry into the Iroquois Confederacy. Seneca material culture begins to correspond closely to that found on eastern Iroquois sites slightly after 1600, perhaps reflecting Seneca participation in the Iroquois Confederacy. When first documented by Europeans, Seneca territory stretched across what is now western New York State from the Genesee River to Seneca Lake; the approximately four thousand Senecas subsisted through agriculture (primarily of maize, beans, and squash), hunting, fishing, and gathering.

Seneca life was altered tremendously by the European fur trade, interaction with European colonial powers, and American territorial encroachment. Senecas began trading beaver pelts for European manufactured goods during the sixteenth century, initially using Native intermediaries. Starting in the 1630s, recurrent European-borne epidemics had major impacts on Seneca communities. Jesuit missionaries resided with the Senecas intermittently from 1668 to 1709. Seneca warriors featured prominently in Iroquois conflicts with the Hurons, Eries, Neutrals, and Susquehannocks from the 1630s through the 1670s. During the seventeenth and eighteenth centuries, Senecas also established satellite communities north of Lake Ontario, at the Niagara portage, and in Pennsylvania and Ohio.

After 1680 the Confederacy and the Senecas increasingly became enmeshed in imperial politics. French forces destroyed all four homeland Seneca villages in 1687. After 1701 Senecas and other Iroquois established a policy of neutrality between European powers, receiving diplomatic benefits by playing European groups off one another. Senecas built smaller, dispersed villages across the region and began producing deerskins for trade with Europeans after 1715. Following the 1760 surrender of New France to Great Britain, Seneca opportunities for diplomatic maneuvering diminished. Western Senecas were key players in the multinational Indian revolt against the British from 1763 to 1766. During the American Revolution (1775–1783), the Senecas sided with Great Britain. American expeditions led by John Sullivan (1740–1795) and Daniel Brodhead (1736–1809) razed approximately thirty Seneca villages in 1779; Seneca survivors spent a difficult winter at Fort Niagara under British protection. Many Senecas subsequently reoccupied their homelands, while others founded new settlements, most notably Buffalo Creek.

From the Revolution to the present day, Senecas have faced major pressures on their lands, resources, and culture from the United States. A series of controversial
treaties and agreements, starting with the Treaty of Fort Stanwix in 1784, divided Senecas and confined them to smaller and smaller reservations. A fraudulent 1838 treaty almost transferred the four remaining Seneca reservations to the Ogden Land Company; a renegotiated 1842 treaty still resulted in the loss of the Buffalo Creek reservation. Following passage of the U.S. Indian Removal Act of 1830, Senecas living in Ohio negotiated exchange of their lands for territory in what is now Oklahoma; their descendants officially formed the Seneca-Cayuga Tribe of Oklahoma in 1937.

Christian missionaries became fixtures on Seneca reservations in the 1790s. In 1799 an Allegany Seneca named Handsome Lake (c. 1735–1815) received visions for a new religious code that reconciled Iroquois traditions with the limitations of reservation life. His teachings (the Gaiwiio) eventually spread to other Iroquois communities. In 1848 Senecas at Cattaraugus and Allegany replaced their traditional government with an American-style elective council; Tonawanda Senecas maintained traditional governance, ending political ties between the groups. The Thomas Indian School, a state-run boarding school promoting Indian assimilation, operated at Cattaraugus from 1855 to 1957. From 1959 to 1964 federal officials took one-third of the Allegany reservation for the construction of the Kinzua Reservoir, forcing relocation of 550 people.

Senecas long have fought American encroachments on their territory and rights. Some efforts have succeeded, including the 1990 renegotiation of non-Indian leases of Seneca property in Salamanca, New York, and the 2002 compact between New York State and the Seneca Nation of Indians that allowed casino development in Salamanca, Niagara Falls, and Buffalo. Other efforts, such as the Seneca claim for Grand Island, have been rejected by American courts. Today, approximately 10,000 Senecas reside in several jurisdictions across the United States and Canada. In New York State, the Seneca Nation of Indians controls territories at Allegany, Cattaraugus, and Oil Spring; the Tonawanda Band of Seneca Indians have a separate reservation. Senecas also reside in Oklahoma and on the Six Nations Reserve in Ontario, Canada. Many other Senecas live off reservations, particularly in Buffalo, Rochester, and Erie.

**SENSATIONALISM**

Certain events, even when reported accurately and without exaggeration, elicit intense reactions. Some such sensational stories—illustrated by O. J. Simpson standing trial in 1995 for a double homicide and R. Gordon Wasson’s description in 1957 of an ancient religious ritual in which psychedelic mushrooms were eaten—are justifiable given the novelty of the phenomena described. Reports tainted by fraud or disregard for truth deserve censure.

Fraudulent reports are often sensational. For example, a *Washington Post* reporter, Janet Cooke, won a Pulitzer Prize in April 1981 for her tall tale about “Jimmy,” an eight-year-old boy allegedly addicted to heroin since age five. Cooke’s story aroused considerable pity among readers. Washington, D.C., Mayor Marion Barry and other city officials promptly started searching for Jimmy, the innocent victim of a heroin dealer. Before Cooke’s fabricated story was published in the *Post* on September 28, 1980, Cooke lied to enlist her editors’ sympathy, claiming she could not reveal her “sources” because she “promised them anonymity and her life was threatened by the drug pushers involved” (Stein 1993, p. 130). Cooke’s credibility was shattered after autobiographical information she supplied to the Pulitzer Prize committee was released—and was proven to be false. *Washington Post* editors subsequently scrutinized some 145 pages of notes and tape-recorded interviews but discovered no evidence that “she actually interviewed a heroin-addicted child” (Stein 1993, p. 131). Cooke confessed and resigned, at the
Post’s request. The Pulitzer Prize was returned, for the first time in its sixty-four-year history.

Mayor Barry, the Pulitzer Prize committee, and Cooke’s colleagues were blinded by their pity for an innocent child, combined perhaps with anger at his mother and the drug dealers blamed for having addicted them. Cooke feigned fear to circumvent her editors’ request that she identify Jimmy and other “sources” for her then unpublished story.

Pity, fear, and anger—powerful emotions Cooke exploited to sell her story—are integral to pathos, an emotionally oriented persuasive device discussed in Aristotle’s *Rhetoric*. The Greek word *pathos* is the root of the English word “pathetic,” a term whose negative connotations imply unjustifiable sensationalism.

Sensational stories often are written by reporters afflicted with excessive pathos, usually arousing the same emotions in their audience that interfered with their own capacity for critical thinking. The “yellow journalism” of William Randolph Hearst and Joseph Pulitzer is a famous example. Their newspapers’ coverage of Cuban-Spanish conflicts between 1895 and 1898 routinely exaggerated the suffering of Cuban rebels in order to arouse pity for them and anger at allegedly tyrannical Spaniards. Anti-Spanish media propaganda involved some deceit, as well as outrageous yet unverified reports, as when the American battleship *Maine* exploded and sank in Havana harbor in 1898. Many reporters, especially Hearst employees, rushed to judgment, proclaiming that Spain had mined the *Maine*, killing 260 Americans. Most historians agree that America’s decision to wage war against Spain was partly the result of such careless reporting. Research conducted in the 1970s concluded that an accident caused the *Maine*’s destruction.

Pathos-driven accounts of breast implants in the 1990s illustrate irresponsible sensationalism without intentional deceit. The journalist John Stossel has explained how and why victims’ anecdotes alleging that silicone breast implants caused cancer and autoimmune disease became fashionable during the 1990s. Scientific facts and evidence were ignored because “the women’s fear and anger were palpable” (Stossel 2004, p. 105). According to doctors, about 1 percent of all women who had breast implants had connective tissue disease. Most reporters saw that as proof of causality, ignoring the fact that 1 percent of all women who had not had transplants also got that disease (Stossel 2004, p. 106). If silicone implants truly cause connective tissue disease, then the percentage of women afflicted by that disease would be significantly higher than the percentage of women who never had breast implants. Media hysteria prompted a federal prohibition on silicone breast implants from 1992 to 2006, unless prescribed for reconstructive surgery following mastectomy.

Anthropologists have been implicated in scandals after publishing controversial claims before diligently attempting to verify their facts. Ashley Montagu, commenting on the anthropologist Robert Zingg’s acceptance of unverified claims about two feral “wolf-children” allegedly found inside a den near a village in India, warned that “no scientist can accept as true any statement … until it has been independently confirmed by others” (quoted in Zingg 2004, p. 233). Zingg’s startling book, *Wolf-Children and Feral Man* (1942), was abhorrent to most social scientists, for whom verification is indispensable to achieving the primary purpose of scientific research: accumulating accurate information.

Margaret Mead’s sensational declaration that Samoan teenagers enjoyed premarital sexual freedom was welcomed by most social scientists eager for evidence that nurture rather than nature produced adolescent stress. Mead’s book *Coming of Age in Samoa* (1928) was, by the 1960s, the most widely read of all anthropology books (Freeman 1996, p. 105). Mead’s seductive story about Samoan sexuality became indefensible after one of her adolescent female informants confessed in 1987 to Derek Freeman (1996, p. viii) that she and a friend had gleefully concocted anecdotes implying that premarital sex was standard Samoan practice. Mead erred by rushing to endorse—and publish—those hoaxers’ accounts, even though, as Freeman notes, her own research data indicated that at least 60 percent of the adolescent females in her sample were virgins.

More infamous anthropological examples of sensationalism involve outright deception. For forty years Piltdown Man, excavated near Sussex, England, was celebrated as the “missing link”; proof that humans evolved from apes. In 1953, scientific tests showed that this six-hundred-year-old skull was spurious; a new orangutan jaw and teeth had been cleverly filed and attached to the human skull. For financial gain, in 1971 Manuel Elizalde fabricated the Tasaday tribe, an allegedly “Stone-Age” people surviving in the Philippines. Carlos Castaneda’s claim, that he was the apprentice of a Yaqui Indian sorcerer, made him a best-selling author and a doctor in anthropology before he was denounced as a hoaxer. Whatever these tricksters’ motives, they intended to benefit by using deception to persuade people that their astonishing allegations were true.

Preventing or reducing the number of reports that are concocted (e.g., Elizalde, Castaneda) or careless (e.g., Zingg, Mead) probably requires both the enforcement of harsher professional penalties for such malpractice and increasing the rewards for researchers (debunkers) whose critical thinking and adherence to high scholarly standards.
advance social scientific knowledge. Deterring journalists from publishing stories infected with unjustified sensationalism, however, will be difficult given America’s deep commitment to freedom of the press and the media’s imperative to sell news. Readers need skepticism and intellectual ability to identify unjustified sensationalism and unverified stories, distinguishing those from honest, verified, and important news or scholarly reports.

SENTIENCE
SEE Consciousness.

SEPARABILITY
Separability is a pivotal economic concept introduced independently by Masazo Sono (1945) and Wassily Leontief (1947) in order to deal with aggregation problems in both utility and production theory. Specifically, this concept was employed by Robert Strotz (1957) to analyze two-stage optimization in utility theory: Given separability, the first stage involves partitioning commodities into subsets and optimizing intensities within each subset. While holding the within-subset intensities fixed, the between-subset intensities are optimized in the second stage.

In formal terms, Leontief and Sono defined two factors $i$ and $j$ to be separable from factor $k$ if and only if

$$
\frac{\partial}{\partial p_i} \left( \frac{\partial C(Y, p_1, ..., p_n)}{\partial p_j} \right) = 0 \quad (1)
$$

where $C(Y, p_1, p_2, ..., p_n)$ is a twice differentiable cost function with nonvanishing first and second partial derivatives with respect to input prices $p_1, ..., p_n$ (Blackorby and Russell 1976, p. 286). A similar definition also applies to an any twice differentiable production function $F(X_1, X_2, ..., X_r)$ (see, e.g., Berndt and Christensen 1973, p. 404).

For aggregation purposes, the economic literature commonly distinguishes strong from weak separability, a terminology coined by Strotz (1957). A cost function $C(Y, p_1, p_2, ..., p_n)$ or a production function $F(X_1, X_2, ..., X_r)$ is said to be weakly separable if condition (1) holds for all $i \in N_j, j \in N_k$ and $k \notin N_i$, where $N_i$ is a subset of the set of input factors $N = \{1, 2, ..., n\}$. Accordingly, cost function is said to be strongly separable if condition (1) holds for all $i \in N_s, j \in N_r$ and $k \notin N_i \cup N_r$, where $N_i$ is another subset of $N$.

Steven Goldman and Hirofumi Uzawa (1964) prove that weak and strong separability impose specific restrictions on the underlying cost and production functions. Weak separability with respect to any partition $R$ of $r$ mutually exclusive and exhaustive subsets $N_1, N_2, ..., N_r$ is necessary and sufficient for a production function to be of the form $F(X_1, X_2, ..., X_r)$, where the aggregate $X_i$ is a function of only the elements of $N_i$. Similarly, strong separability implies that the production function is of the form $F(X_1 + X_2 + ... + X_r)$.

In empirical applications it is often indispensable to invoke separability assumptions if data on some production factors are lacking. For instance, numerous empirical studies investigating the substitutability of capital ($K$) and labor ($L$) have assumed that both inputs are weakly separable from energy ($E$) and materials ($M$), implying the so-called “value-added” specification of production technologies, $F(V = G(K, L), E, M)$. This assumption, it is commonly asserted, allows for focusing on the capital-labor aggregate $V = G(K, L)$ when estimating the degree of substitution between capital and labor, whereas energy and materials inputs can be safely ignored (Berndt and Wood 1975, p. 265).

This example illustrates that the concept of separability is intimately associated with the notion of substitutability of production factors and consumer goods (see, e.g., Berndt and Christensen 1973 and Blackorby and
Russell 1976). The natural intuition about the separability of a nonnegligible production factor, such as energy after the oil crises, from all other factors is that the substitution elasticity estimates of nonenergy inputs remain the same, irrespective of whether energy is included in any substitution analysis (Hamermesh 1993, p. 34).

This intuition, however, does not apply to the typically employed substitution measures, such as the Allen and Morishima elasticities of substitution, or cross-price elasticities, because the classical Leontief-Sono condition (1) only implies that the input proportion \( x_i \) remains unaffected by changes in the price \( p_i \) of factor \( k \):

\[
\frac{\partial}{\partial p_k} \left( \frac{x_i(p_1, p_2, \ldots, p_n)}{x_j(p_1, p_2, \ldots, p_n)} \right) = 0, \quad (2)
\]

where Shephard’s Lemma \( \frac{\partial C}{\partial p_i} = x_i \), has been inserted into condition (1). When replacing the cost function by its dual production function \( F(x_1, x_2, \ldots, x_n) \), the primal analogon of condition (1) suggests that the marginal rate of substitution between any two inputs \( i \) and \( j \),

\[
\frac{\partial F(x_1, x_2, \ldots, x_n)}{\partial x_i} \frac{\partial F(x_1, x_2, \ldots, x_n)}{\partial x_j},
\]

is independent from the input \( x_k \) of factor \( k \) (Berndt and Christensen 1973, p. 404).

Yet, virtually no empirical study measures the ease of substitution between \( i \) and \( j \) in terms of either their input proportion or their marginal rate of substitution. Manuel Frondel and Christoph Schmidt (2004) therefore suggest an empirically oriented definition of separability that guarantees the invariance of cross-price elasticities

\[
\eta_{i,j; p} := \frac{\partial ln x_i}{\partial ln p_j} \text{ and } \eta_{j,i; p} := \frac{\partial ln x_j}{\partial ln p_i} \text{ due to changes in the price } p_i.
\]

It can be shown that this definition represents a stronger requirement than the classical Leontief-Sono separability condition (1). In other words, the Leontief-Sono condition (1) is necessary, but not sufficient, for the separability definition (3) to hold (Frondel and Schmidt 2004, p. 221). Frondel and Schmidt (2004, p. 220) argue, however, that only these stronger conditions capture a separability notion coming close to Hamermesh’s (1993) intuition.

**SEPARATE-BUT-EQUAL**

During the post–Reconstruction era, southern states passed laws reestablishing white advantages and privilege by reviving pre–Civil War practices requiring blacks and whites to attend separate schools, ride in separate train cars, and sit in separate sections of theaters. Soon after the Interstate Commerce Commission (ICC) was created in 1887, it received complaints from blacks who had purchased first-class train tickets but were forced to ride in less comfortable dirty train cars reserved for blacks only. In response, the ICC ruled that in trains under its jurisdiction, if racial segregation was practiced, then equal-quality cars must be provided for “white” and “colored” races. Louisiana (and other southern states) then passed laws stipulating that “all railway companies carrying passengers in their coaches in this State shall provide equal but separate accommodations for the white and colored races, by providing two or more passenger coaches for
each passenger train, or by dividing the passenger coaches by a partition so as to secure separate accommodations. No person or persons shall be admitted to occupy seats in coaches other than the ones assigned to them on account of the race they belong to."

In a U.S. Supreme Court case of tremendous importance, *Plessy v. Ferguson* (1896), Homer Plessy, a black man, challenged that Louisiana law. He argued that enforcing where people should sit based solely on their race was an unconstitutional violation of citizens’ rights; for example, the Fourteenth Amendment prohibits laws that abridge the privileges or immunities of U.S. citizens or deny people equal protection of the laws. The Supreme Court’s decision, however, rejected Plessy’s claim, and, for the next sixty years, its ruling that “separate-but-equal” segregation is permissible and not harmful was the foundation on which racial segregation was legitimized.

*Plessy v. Ferguson*’s doctrine of “separate-but-equal” racial segregation rested on three closely related arguments, each of which was later challenged by civil rights proponents. First, the Court argued that the Fourteenth Amendment only guarantees that blacks and whites have equality with regard to political rights (e.g., to vote or hold office) and legal rights (e.g., to serve on juries, to own property), not with regard to social rights or social equality. Second, *Plessy v. Ferguson* asserted that state governments had the right to permit or require racial separation provided that the segregation laws are “reasonable” and “enacted in good faith for promotion for the public good, and not for the annoyance or oppression of a particular class.” Third, this “separate-but-equal” doctrine contended that enforced separation of the races did not stamp the colored race “with a badge of inferiority.” Instead *Plessy v. Ferguson* claimed that if the two races are socially unequal, this inequality is the result of “racial instincts” that either put one group lower than the other or cause people to believe they are superior or inferior, and the Court held that altering either of these is beyond the power of legislation or judicial decision-making—that is, that “natural” inequalities and prejudices linked to race can not be overcome by government-required cointerning of the two races.

What is evident in *Plessy v. Ferguson*’s “separate-but-equal” doctrine is the absence of a serious concern about whether the separate facilities assigned to “white” and “colored” races really were of equal quality. Nowhere in the Court’s decision is there mention of any test to be used to judge whether the separate facilities are in fact equal, nor is there a clear statement directing those in authority to provide equal facilities to both races. In fact, shortly after *Plessy v. Ferguson*, the Supreme Court ruled on whether a board of education in Georgia was required to provide a high school for blacks since they did so for whites. The Court ruled that the school board did not have to do so, and this decision (*Cumming v. Richmond County Board of Education*, 1899) became a precedent for providing “separate and unequal” facilities to blacks.

**CONSEQUENCES**

The legacy of “separate but (un)equal” was that white-dominated state and local governments created and institutionalized a gulf or color line in public life separating blacks and whites. W. E. B. Du Bois, in the early 1900s, called this color line “the problem of the 20th century” (Du Bois 1901). Gross inequalities were permitted under the guise of “separate but equal.” In health care, hospitals and doctors in the North and South routinely refused to treat blacks in need of medical attention, and black medical students were denied training and internship experience in “white” hospitals. In education, southern states in the 1930s spent for blacks’ education less than one-third what they spent for whites. Residential neighborhoods and housing policies were organized to exclude blacks from the better areas and prevent them from living among whites, for example, by racial zoning ordinances, racially restrictive covenants, discriminatory mortgage lending, and outright refusal to rent apartments or sell homes to blacks. Atlanta blacks comprised one-third of the city’s population but resided on less than 20 percent of its land—the most overcrowded and run-down areas. Residential segregation was not just a southern phenomenon; in the 1940s and 1950s many northern cities, including Chicago, Cleveland, and Detroit, were among the most highly segregated cities (and remained so in the mid-2000s).

Perhaps the most visible consequence of the “separate but (un)equal” color line was the demarcation of “white” and “colored” public spaces in parks, beaches, movie theaters, sports stadiums, restaurants, buses and transit waiting rooms, restrooms, and water fountains. People of color who transgressed the color line by using a facility reserved for whites were frequently arrested, jailed, physically beaten, or killed by the police or by secretive groups of whites who took it upon themselves to guard racial boundaries.

Another consequence of racial segregation imposed by the “separate but (un)equal” doctrine was the development of notable African American communities in most large U.S. cities. As migrating blacks were forced into a few neighborhoods, their growing numbers and initiatives for survival and success expanded many black institutions that would greatly influence local (sometimes national) cultural, social, economic, and political life. Amid squalor and poverty in these African American districts arose successful banks and businesses, vibrant churches, innovative music and arts scenes, active social and labor groups, and
organizations devoted to racial solidarity, uplift, and the struggle against racism. In well-known black communities, such as New York’s Harlem, and in less well-known ones, the broadened social-class structure, the accumulation of resources, and development of leadership gradually stimulated a movement that would challenge and defeat state-sponsored racial segregation.

Although the “separate but (un)equal” doctrine originated from whites’ racial prejudices, once institutionalized it nurtured and amplified racial prejudices, mainly in two ways. First, by denying blacks opportunities for good education, jobs, homes, medical care, and social dignity, it forced many into impoverishment and desperation, and many whites interpreted behavioral symptoms associated with this as a sign of black inferiority. Second, isolating blacks from whites prevented the kind of social interaction that can dispel prejudice, that is, equal-status intergroup cooperation toward common goals, which reveals personal information that disconfirms common negative stereotypes.

OVERTURNING “SEPARATE BUT (UN)EQUAL”

In a limited sense the Brown v. Topeka Board of Education (1954) decision overturned the “separate but (un)equal” doctrine. It dealt with de jure segregation in public schools, in which governmental agents (school boards) required blacks and whites to attend different schools. The Court ruled this an unconstitutional violation of blacks’ Fourteenth Amendment rights because it “has a detrimental effect upon the colored children” in that it suggests an inferiority among blacks that weakens their motivation to learn and negatively affects their hearts and minds, thereby depriving them of equal educational opportunity. Because of delaying tactics by many state and local officials, little racial integration occurred in schools for ten years. In truth, the Brown decision was the tip of the iceberg that punctured the “separate but (un)equal” doctrine. It was based on prior precedent-setting lawsuits by the National Association for the Advancement of Colored People (NAACP) that challenged racial segregation and on the dissemination of psychological and sociological research on the negative effects of racial segregation. Finally, and perhaps most importantly, victory against segregation beyond the schools was the product of social activism and pressure created by public protests, boycotts, and disruptions of the status quo (including the Montgomery bus boycott, sit-ins, and riots after the assassination of Dr. Martin Luther King Jr.) that forced many authorities to see that they had more to lose than to gain in preserving state-sanctioned racial segregation.

SEPARATION ANXIETY

Separation anxiety is characterized by infants’ and toddlers’ intense emotional reactions to the departure of a person with whom they have established an emotional attachment. Having its roots in psychodynamic theory, according to which infants’ attachment to their mothers is a learned response to being fed, the ethological theory of attachment (Bowlby 1980) frames the development of emotional attachment as an innate behavioral need that not only satisfies infants’ hunger, but also keeps them safe from danger and allows for a secure base from which they can explore their surroundings. According to attachment theory, separation anxiety is a normal developmental stage in which infants have formed a representation of their caregivers as reliable providers of comfort and security.

The strange situation procedure (Ainsworth et al. 1978), in which infants and toddlers are observed during brief separations from and reunions with the parent, is often used by researchers to determine if infants have reached the stage of separation anxiety and if their attachments with caregivers are healthy and secure. Using such procedures, researchers have found that separation anxiety is a fairly universal phenomenon that emerges around six to eight months, with signs of distress peaking around fourteen to twenty months, at which age toddlers may follow or cling to caregivers to prevent their departure.

Typically, separation anxiety lasts only a few minutes; however, many factors, such as tiredness, illness, changes in the household routine, family changes such as birth of
a sibling, divorce, death, or a change in caregiver or routine at a day-care center, can contribute to more intense episodes. The intensity of distress also varies depending on: (1) the availability of another person with whom the child has a close bond; (2) the familiarity of the situation; (3) previous experience with the caretaker leaving; and (4) the child’s sense of control over the situation. Separation anxiety diminishes as children develop a sense of safety and trust in people other than parents, become familiar with the environment, and trust in the parent’s return.

Although separation anxiety is part of normal development for infants and toddlers, for older children, adolescents, or adults such anxieties and behaviors may represent symptoms of a serious disorder known as separation anxiety disorder, or what are also referred to as disorders of attachment. In addition to excessive distress when separated from the primary caregiver, symptoms of disorders of attachment include sleep disturbances such as difficulty falling asleep, nightmares, or fears at bedtime; depressed or withdrawn behavior; apathy; difficulty concentrating; and somatic complaints (e.g., dizziness, nausea, or palpitations). Children may also fear losing the parent or worry about the parent being harmed. Their need to stay close to the parent or home makes it difficult to form healthy relationships with others, such as peers or teachers. Older individuals with separation anxiety disorder may have difficulty moving or getting married and may, in turn, worry about separation from their own children and partner. To reach the diagnostic threshold for this disorder, the anxiety or fear must cause distress or affect social, academic, or job functioning.

**SEPARATION OF POWERS**

The separation of powers is normally understood as a constitutional doctrine according to which political freedom is best guaranteed by separating the powers of government into legislative, executive, and judicial branches, each with its own jurisdiction. The purpose of this arrangement is to ensure that no single group or individual can control all the levers of power and, thereby, rule despotically. The legislature has primary responsibility for lawmaking, while the impartial interpretation of the law and the application of it to particular cases falls under the purview of the judiciary. The executive must obey the rules established by the legislature and enforced by the judiciary.

Charles-Louis de Secondat, baron de Montesquieu (1689–1755), provided the separation of powers with its canonical statement in *The Spirit of the Laws* (1752), but early intimations of the idea can be found in ancient Greece and Rome, where the systematic study of constitutions first began. Aristotle was the first comparative political thinker to notice that all constitutions have deliberative, judicial, and executive elements. Although he did not argue that government should be organized into separate branches, he believed that different types of constitutions (democratic, aristocratic, or monarchic) should be “mixed,” so as to counteract the tendencies to corruption inherent in all pure constitutions. Greek historian Polybius (c. 200–c. 118 BCE) used this theory to explain Roman history, as did Renaissance Florentine thinker Niccolò Machiavelli. The immediate precursor to the development of the separation of powers, however, was seventeenth-century English political thought, particularly the work of John Locke.

The separation of powers is an inherently conservative doctrine, in that it was intended to prevent the use of state power to promote radical social change, and yet it contributed to the rise of constitutional democracy. It offered a constitutional design that promised simultaneously to check monarchical abuses of power and limit the growing ambitions of legislators. It appealed to the nobility, who felt squeezed between overweening absolutist monarchs and pressures to expand popular participation. Although the separation of powers is not a theory of democratic government—it can be, and was, adopted by constitutional monarchies—it gave impetus to the spread of democracy by offering a way of reconciling the will of the people with the rule of law. As such, the doctrine was celebrated in the *Declaration of the Rights of Man and the Citizen* (1789) during the French Revolution, and it was the subject of intense debate by the framers of the Constitution of the United States.

Over the course of the nineteenth century the doctrine lost relevance, and its meaning was gradually restricted to a more specific distinction among types of democratic constitutions—specifically, presidential versus parliamentary government. Critics of Montesquieu charged that he had misread the English constitution, by
failing to appreciate how in Westminster parliamentary systems the legislature and executive were fused in the cabinet and in the office of the prime minister. Such a fusion of powers made parliamentary systems elective dictatorships, or so claimed the critics. The Constitution of the United States, with its separate election of president and congress, came to be seen as the closest approximation of the separation of powers.

Montesquieu’s critics misunderstood the separation of powers, however. They imagined a watertight separation of branches of government in which no person or group could be a member of more than one branch at a time and no branch could encroach upon the powers of another. This view, which is more of a caricature than a description of any observed political system, had no expositors: No major constitutional theorist ever called for such an absolute separation. James Madison (1751–1836) was the first to reject this caricature, not only because it misrepresented Montesquieu, but, more importantly, because the partial encroachment of branches of government was necessary as a check against the abuse of power: Ambition should counteract ambition; checks and balances, rather than watertight separation of branches of government, would limit tendencies toward abuse of power. Madison was firmly of the same mind as Montesquieu in his conviction that only power can check power.

In the twentieth century the idea of the separation of powers continued to occupy a respected place in legal scholarship and jurisprudence, but lost appeal among social and political theorists. The development of the administrative functions of the state, especially with the expansion of the welfare state, placed more public-sector activity outside the sphere of legislation and into the hands of specialized agencies and experts. The rise of totalitarianism by electoral means in Italy and Germany suggested that the separation of powers was a feeble bulwark against modern antidemocratic and illiberal movements. Political freedom depended more on the degree of social and economic equality, the competitiveness of political-party systems, and a culture of constitutionalism, than on the constitutional separation of powers. Above all, as political science became a more scientific discipline, the language of the separation of powers seemed outdated and formalistic. A new view of institutions arose, building on economic and organizational theory, in which the separation of powers was understood to mean the separate election of executive and legislature in a presidential system of government.

The Anglo-American tendency to treat the separation of powers as a virtual synonym of presidentialism has been resisted by continental political theorists, especially in recent work on deliberative democracy. German philoso-
SEPARATISM

Separatism is the ideas or activities advocating separation of a group or a territorial unit from a state (country), state institutions, or a larger group, usually in the form of autonomy or independence. Examination of complex relationships between the intensity of separatism and its goals and motivations cross-nationally or within individual states is one of the central lines of inquiry in social sciences. Systematic analyses of this phenomenon are available in political science, sociology, anthropology, social psychology, and geography.

With regard to intensity, scholars distinguish between latent separatism in the form of beliefs, attitudes, narratives, ideologies, as well as collective memories of past autonomous or independent status, and active separatism that can be peaceful (petitions, noncompliance with national laws, formation of separatist movements, and rallies or demonstrations) or violent (destruction of property, beatings, riots, guerrilla attacks, terrorist acts, and civil wars). The intensity of separatism also relates to the scale and nature of separatist demands. At the lowest end of the scale are group- or community-level demands for a larger share of economic revenues or for enhancing the status of their culture and lifestyle that do not involve changing the constitutions or other legal foundations of a nation-state. Examples are most manifestations of municipal or tribal separatism in the United States; provincial separatism in Europe, China, and the Russian Federation; and sectarian dissidence (e.g., Nation of Islam in the United States, Old Believers in the Russian Orthodox Church). In the latter case, sectarian refers to breaking away from the main arm of the group’s base religion and dissidence refers to these groups seeking to stand apart from society and government in important ways.

At a higher level are demands to change constitutions or other fundamental state laws to decentralize government authority within a state in favor of constituent administrative units (provinces), usually with respect to electoral processes, government appointments, taxation, control over natural resources and principal economic activities, language use, education, regulation of churches, and other cultural and symbolic issues. In the late twentieth and early twenty-first centuries this type of separatist demand was systematically illustrated by the movement known as the “parade of sovereignties” in post-Soviet Russia (1991–1999). This movement resulted in a negotiated federal treaty, a redefinition of the political status of Russia’s eighty-nine constituent units (provinces, republics, and districts) in the Russian constitution, and the signing of power-sharing treaties between the federal government and more than fifty constituent unit governments.

The strongest form of separatism is demand for independent statehood (full secession), complete with granting the separatist units the monopoly on legitimate use of violence within its borders and international recognition of the new state’s sovereignty. Reflecting the drive for self-determination, these demands take the form of civic or ethnic nationalism or, typically, a combination of both. Prominent examples at the global level both past and present are separatist movements in Spain (Basques), Canada (Quebec), Turkey (Kurds), Great Britain (Northern Ireland), the Soviet Union (Estonia, Lithuania, Latvia), the Russian Federation (Chechnya), former Yugoslavia (Croatia, Kosovo, Bosnia, Slovenia), Georgia (Abkhazia, South Ossetia), Indonesia (Aceh, East Timor), China (Tibet, Xinjiang), India (Kashmir), Mexico (Chiapas), Nigeria (Biafra), Ethiopia (Eritrea), the United States (the Confederacy), and elsewhere. In the majority of cases where these types of secessionism claims have had strong social support, they have also been accompanied by mass political action, from demonstrations and referenda to the formation of rebel armies and protracted wars.

SEPARATISM: A COMPLEX AMALGAM

Most separatist ideologies or movements are complex amalgams of political, ethnic/racial, religious, and socioeconomic separatisms. Only rarely does one find any of these distinct forms of separatism in their pure form. Political separatism represents contestation over the design and control of political systems and their constituent institutions. Mobilized political ideologies are paramount. This was the case of monarchist, socialist, and liberal-democratic separatist movements that seized power in provincial governments and mobilized military forces to unsuccessfully contest the Bolshevik takeover of Russia’s central government in November 1917. The central element of the separatist movements that later galvanized the disintegration of the Soviet Union was anti-communism. The latter enabled the coming together of pro-democracy and nationalist movements that had few reasons to join forces otherwise. Russia’s first elected president, Boris Yeltsin, mobilized a distinctly anti-Soviet separatist movement advocating secession from Soviet institutions, such as the Communist Party, the KGB (the security and intelligence organization of the Soviet Union), and the state planning agency.

Ethnic, racial, and religious separatism presupposes claims for enhanced status, autonomy, or independence of individual ethnic, racial, or religious groups from the state or a larger group. At the center of ethnic/racial movements are claims to cultural and/or linguistic distinctiveness and privilege (as in Quebec, Basque Country, and Corsica). Religious separatist movements arise within major religions (Catholic-Protestant conflict in Northern Island, Shiite-Sunni conflict in Iraq) or across major reli-
regions (Hindu-Muslim conflict over Kashmir, Islam-Christianity distinctions in Bosnia). In their most extreme form these movements claim the need to ensure physical survival of an entire ethnic/racial and/or religious group (Abkhazia, Chechnya, Xingjiang). Separatism of ethnic, racial, and religious minorities may also take a form of resistance to discrimination, oppression, forced resettlement, ethnic cleansing, or mass extermination initiated against them by the politically dominant ethnic or racial groups within a state (i.e., those who control the army, police, security forces, mercenaries, and paramilitaries). In the latter instances, separatist conflicts become particularly intense, brutal, and protracted as action-retribution patterns escalate, become intractable, and constrain conflict resolution efforts by third parties within or outside the state. One of the prominent empirical questions in social sciences is to what extent the intensity of separatist movements depends on whether ethnic, linguistic, religious, and other identity cleavages in a society are cross-cutting (India) or overlapping (Russia). Economic separatism, on the other hand, is typified by the slogan of the American colonists seeking independence from the British Empire—"no taxation without representation"—but when economic interests are predominant, separatist movements are more likely to end in bargains with central authorities rather than in state disintegration.

MOTIVATION BEHIND SEPARATIST MOVEMENTS

Social scientific research identifies three sources of motivation behind separatist movements: (1) structural conditions (macroeconomic performance and intergroup differentials, demographic trends and distribution of ethnic populations, polity type, ethnofederalism, geography and terrain); (2) behavioral microfoundations (intergroup bias, frustration-aggression psychology, cognitive processes, emotions); and (3) interactivity (bargaining or "games" within and outside the state, conflict precedent, demonstration effects). Debates within and across disciplines are predominantly about the relative importance of these factors. Research methodology includes ethnographic accounts; historical case studies; small-group experiments; and statistical analysis of surveys, aggregate statistics, and event data. Examples of the latter are the Minorities at Risk, State Failure Task Force, and Global Events Data Systems projects based in the United States, which draw on large datasets documenting cases of separatism from nation-states or empires throughout the world from 1800 to the early 2000s.

SEPTEMBER 11, 2001

On September 11, 2001, or “9/11,” a series of terrorist attacks on the United States killed approximately 3,000 people. On a sunny Tuesday morning four commercial airplanes were hijacked and used as flying bombs to destroy prominent symbols of American economic and political power. The plan, a coordinated attack conducted by four separate teams of hijackers with at least one in each team trained in the basics of airplane flight, commandeered American Airlines flight 11, United Airlines flight 175, American Airlines flight 77, and United Airlines flight 93. They flew two of the aircraft into the Twin Towers of the World Trade Center in Manhattan, New York, and one into the Pentagon in Washington, D.C. The fourth plane, United flight 93, after a violent struggle between the passengers, crew, and hijackers, did not reach its intended target and crashed into a field in rural Pennsylvania.

THE ATTACKS

Two of the early-morning flights, flights 11 and 175 from Logan Airport in Boston and bound for Los Angeles, were hijacked soon after takeoff at 8:00 and 8:15. Flight 77
from Dulles Airport in Washington, DC, also bound for Los Angeles, was hijacked soon after takeoff at 8:10. The fourth plane, flight 93 from Newark Airport in New Jersey, bound for San Francisco, was hijacked after takeoff at 8:40. The planes, loaded with fuel for lengthy cross-country flights, were selected to create maximum destruction on their targets. The hijackers, carrying mace or tear gas and box-cutter knives and claiming to have bombs, took control of the aircraft after killing or assaulting the pilots, flight attendants, and at least one passenger.

Flight 11, reported by morning commuters to be flying at a dangerously low altitude south along the Hudson River in New York, veered east over lower Manhattan before crashing into the North Tower of the World Trade Financial Center (WTC) at 8:46. At approximately 9:02 flight 175 crashed into the South Tower of the WTC. The crash of the second plane was seen live on television by many who were watching the news of the first crash, including the parents of one of the passengers on United 175, who were on the phone with their son, who was calling from aboard the doomed plane. Throughout the day television stations broadcast live images of the morning attacks and the human tragedy that ensued.

Many inside the WTC, believing they would quickly be rescued, were instructed not to evacuate the building. Soon hundreds of New York City firefighters and police and Port Authority Police officers descended on the scene to provide assistance, attempting to fight the fires that quickly engulfed the buildings and evacuate the surrounding area. While some in the office complex fled safely, thousands remained in the building, trapped by fire and smoke. Hundreds watched in shocked disbelief from the streets below as people jumped to their deaths from the burning buildings. Those trapped on the floors above the flames tried to make their way to the roofs of the towers in the vain hope they would be rescued, only to perish as the smoke and heat overcame them in locked stairwells.

At 10:05, the South Tower of the WTC, crippled by the intense jet-fuel-fed fire that destabilized the structure, collapsed. A massive cloud of debris and smoke surrounded the area. Less than thirty minutes later the North Tower collapsed, sending more debris and smoke into the air. Within minutes Lower Manhattan was enveloped in a dark plume of debris and smoke. Most of the rescuers who entered the building lost their lives, including 343 members of the New York City Fire Department, twenty-three New York City police officers, and thirty-seven Port Authority police. Additionally, over 2,000 people in the towers or on the ground were killed. Among those who evacuated the buildings immediately following the attacks, many expressed both sadness and admiration for the rescue personnel who had entered the burning buildings to battle the fires and assist the injured, many of whom had called emergency service operators to plead for assistance until the moment the buildings collapsed.

While these events unfolded in New York City, another hijacked plane, flight 77, crashed into the Pentagon at 9:37, killing all aboard and 125 civilian and military personnel on the ground. At 10:03, about the same time the South Tower of the WTC collapsed, the last of the four hijacked aircraft crashed into a field in rural Pennsylvania, killing all forty-four people aboard. Flight 93 crashed after numerous passengers learned from family and coworkers on the ground through cell phone calls that other planes had been hijacked earlier and flown into buildings. The passengers tried to overpower the hijackers and regain control of the plane to avoid further attacks. The crash was believed to have occurred as a result of the hijackers either deliberately crashing the plane or losing control of it. The National Commission on Terrorist Attacks Upon the United States, referred to as the 9/11 Commission, later issued a report determining that flight 93 was targeted to hit the U.S. Capitol.

The events of September 11 were marked by confusion and error at the highest levels of government and in the media. Conflicting and erroneous reports about additional hijackings or explosions were rife on the morning of September 11. The 9/11 Commission later outlined the national government’s breakdown in general command, communication, and control. At the time of the attacks in New York City, Mayor Rudy Giuliani emerged as a symbol of grace under pressure as he appeared throughout the day and into the night on television and radio from the devastated site to reassure New Yorkers that the city would endure. In the days and months to follow New York City was overwhelmed with support and assistance from construction, health care, police, fire, and rescue personnel from governments and individuals around the world, many of whom came to Manhattan with no intention but to selflessly assist in the recovery effort. For months after the attacks, many people sought out assistance from mental health professionals to cope with the events and the impact it had on their lives. New York City residents often refer to their life experiences as either pre- or post-9/11.

**MOTIVES**

The September 11 attack was not the first terrorist attack against the WTC. In 1993 an explosives-laden truck detonated in the center’s underground parking garage, killing six and injuring hundreds. In the aftermath ten men were arrested, tried, and sentenced to life in prison. Investigation revealed that the terrorists intended to damage the WTC enough so that it would collapse. The terrorist organization that funded the attack, Al-Qaeda, initially a collection of loosely aligned Islamic paramilitary organizations, had formed in the 1980s in response to the
Soviet Union’s occupation of Afghanistan, later broadening its activities to include the United States for its support of Israel and for having troops stationed in Saudi Arabia. Osama Bin Laden emerged as the leader of this group in 1988.

Al-Qaeda had carried out numerous attacks against the United States dating back to 1992. It bombed hotels in Yemen where U.S. troops routinely stopped; it supported groups battling U.S. forces in Somalia in 1993; it carried out car bombings in Saudi Arabia outside a joint Saudi-U.S. facility in 1995; it detonated a truck bomb outside a residential complex that housed U.S. soldiers in Saudi Arabia, killing nineteen, in 1996; it bombed U.S. embassies in Tanzania and Kenya in 1998; it conducted the attack on the USS Cole, a destroyer docked in Yemen, killing seventeen and wounding forty, in 2000. In a 2004 statement, Bin Laden acknowledged Al-Qaeda’s involvement in many of these earlier attacks, including the attacks of September 11.

RESPONSE

In the aftermath of the September 11 attacks, President George W. Bush’s approval ratings soared. Some criticized the president for not being decisive on the morning of the attacks after he was seen on television visiting with grade school children in Florida and later in the day flew from Florida to Louisiana and then Nebraska before returning to Washington, D.C., in the evening. On October 7, 2001, after the United States declared a war on terrorism, a U.S.-led coalition launched an invasion of Afghanistan called Operation Enduring Freedom in an effort to capture Bin Laden and eliminate his base of support. The invasion failed to capture Bin Laden but did topple Afghanistan’s Taliban government, which was believed to have supported Bin Laden and Al-Qaeda. Later, in March 2003, another U.S.-led coalition initiated Operation Iraqi Freedom, an attack on Iraq in an effort to eliminate alleged weapons of mass destruction and Iraq’s alleged support for international terrorism. No weapons of mass destruction or evidence of Iraq’s cooperation with international terrorist organizations were proven, but Iraq’s government under Saddam Hussein collapsed. A French citizen, Zacarias Moussaoui, arrested in August 2001 on an immigration violation after trying to enroll in flight training courses, was convicted of conspiring to kill Americans as part of the September 11 terror attacks. He is now serving a life sentence in a federal prison in Colorado as the only person convicted of the crimes that occurred on September 11.

In the aftermath of the attacks the U.S. Congress passed the USA Patriot Act, increasing the power of the federal government, particularly the executive branch. Congress also created the Department of Homeland Security and facilitated a greater role for the National Security Agency, the nation’s leading eavesdropping organization, in the pursuit of terrorism both within the United States and abroad. Some of the president’s aggressive assertions in the war on terror, including the establishment of military commissions to try suspected terrorists, were later determined by the U.S. Supreme Court to be unconstitutional violations of executive authority.

SEQUOYAH
c. 1770–1843

Sequoyah, a Cherokee also known as George Guess, Guest, or Gist, developed a Cherokee syllabary that brought literacy to his people. Sequoyah’s mother was Cherokee and a member of the Paint clan, one of the seven Cherokee clans; she was descended from Oconostota, an eighteenth-century warrior and ruler. His father’s lineage is uncertain. Some scholars claim he was George Guess, a German trader, or Nathaniel Gist, friend of George Washington. Sequoyah was born near the ancient capital Echota and Fort Loudon (in the vicinity of Tellico Blockhouse in Monroe County, Tennessee) on the Little Tennessee River among the Overhill or Upper Cherokees. In the early 1800s, seeking to avoid attacks from marauding settlers, he migrated with fellow Cherokees to the southernmost edge of the Cherokee Nation and made his home at Willstown, in present-day Dekalb County (Alabama). Though lame, during the War of 1812 he was a horse-mounted combatant serving in the
Sequoyah

Cherokee regiment under Colonel Gideon Morgan. As part of a campaign directed by General Andrew Jackson, he fought against the Alabama Red Stick Creeks in the Battle of Horseshoe on March 27, 1814.

In his private life Sequoyah sought solitude, partly because of his lameness, but also because he wished to develop his talents as a silversmith engraver. Sequoyah's involvement with engraving spurred his intense interest in "talking leaves," the term he used for written material, and in classical and European writing conventions. Though opposed in his efforts by his first wife and neighbors, he began to create his writing method in 1809 and finished his arduous task ten years later, with assistance from his young daughter. He started with a pictograph system and ended up with a system using true phonetic symbols.

Though not an English speaker, Sequoyah recognized the power that written speech, or "talk on paper," could bring to those who had previously only transmitted ideas orally. In 1821 he introduced his syllabary, representing consonant-vowel combinations, six vowels, and the consonant ș. Sequoyah and his young daughter first showed the system to Sequoyah's cousin, George Lowery. Mike Waters, the brother of Sally Waters, Sequoyah's second wife, was the first person to learn the syllabary. The initial Sequoyahan composition dealt with the boundary lines between the Cherokee Nation, Georgia, and Tennessee. A short time later Sequoyah brought a suit in Indian Court, held at Chattooga (northeastern Georgia), and presented his case by reading aloud from a document written in his syllabary. The audience was amazed and news of his invention spread quickly. Within months, the Cherokees had attained literacy. This was impressive not only for Sequoyah's ability to instill Cherokee literacy, but also for the efficiency with which the Cherokees learned the syllabary.

In 1823 Sequoyah left the Cherokee Nation in the Southeast to live with his kinsmen who migrated westward and settled along the Arkansas River, near present-day Indian Territory. He continued to teach his syllabary to the western Cherokee. In recognition of his contributions, Sequoyah was invited to Washington, D.C., in 1825 to receive $500 from Congress; once there, he had his portrait painted by the famed Charles Bird King. Sequoyah became an Indian activist. In 1828 he traveled to Washington, D.C., as a delegate representing some eight thousand Cherokees in land negotiations with the U.S. government in the Treaty of 1828. He was successful in adjudicating contested Arkansas lands claimed by the Osages for exchange of lands beyond the Arkansas River (present-day Oklahoma).

That same year the Cherokee National Council at New Echota (Georgia) acquired a printing press and had type cases set in both Sequoyahan and English characters, creating the only bilingual Indian newspaper, the Cherokee Phoenix. The newspaper, printed partially in the syllabary, contained Cherokee shamans' sacred formulae used for ceremonial purposes, as well as accounts of the manners and customs of the Cherokee. It also featured news of the day and political announcements about district candidates for National Council seats, and printed the 1827 Cherokee Constitution establishing a republican government. The press brought literacy to the illiterate and turned out more than 225,000 pages before Georgia citizens seized it in 1834 because of the Cherokee Phoenix's anti-Indian removal editorials. Because he had already left the Southeast, Sequoyah escaped the bitter factionalism that marked the declining days of the Cherokee Nation (East) after U.S. policymakers forced Cherokees out of their ancestral lands in 1838 in a relocation known as the Trail of Tears.

After Cherokees reunified their nation in Indian Territory, Sequoyah's syllabary was the nucleus of unification for both traditional and acculturated Cherokees. On December 29, 1843, survivors of the removal and Old Settlers, Cherokees who had moved to Indian Territory before mandatory displacement, bestowed upon their beloved scholar a lifetime annual income of $300, probably the first literal pension in American history. Ever mindful of his fellow Cherokees' welfare, Sequoyah constantly taught the syllabary, both to Cherokees in Indian Territory and to those living beyond its borders. Sequoyah left the Cherokee capital, Tahlequah (in Oklahoma), with his son Teesy in an oxcart for Mexico, where he hoped to teach the syllabary to Mexican Cherokees. On his way to Mexico, he visited with Texas Cherokees, who were plotting revenge against Texan residents who had killed many of their relatives, and convinced them to join the members of the recently restored Cherokee Nation (Tahlequah). After reaching northern Mexico, Sequoyah became deathly ill; he died in 1843 and was buried in a cave near San Fernando de las Rosas.

Today, Sequoyah's syllabary is central to the educational programs of both the Cherokee Nation Tahlequah (in Oklahoma) and the Eastern Band of Cherokees (in Cherokee, North Carolina), the latter being remnant Cherokees not included in the compulsory removal of 1838. Cherokee education includes total immersion in the syllabary beginning at a very young age. Literacy in the syllabary is also enhanced by two Cherokee publications, the Cherokee Phoenix (Tahlequah) and the Cherokee One Feather (Cherokee, North Carolina); both papers print in the historical bilingual tradition. Correspondence between East and West Cherokees is greatly facilitated by the syllabary, both because it is so widely studied and because its efficiency permits Cherokees to become proficient writers after a few days' study. Indeed, Sequoyah's syllabary has contributed in no small way to the cultural
revitalization that reverberates throughout both Cherokee domains.

**SERBS**

Serbs are South Slavic people who predominantly live in Serbia, Montenegro, Bosnia-Herzegovina, and Croatia. They are also a significant minority in the Republic of Macedonia and Slovenia.

Serbs constitute about 66 percent of the population of Serbia. The largest urban populations of Serbs in the former Yugoslavian region are in Belgrade and Novi Sad (in Serbia) and in Banja Luka (in Bosnia-Herzegovina). Serbs are also present as a sizable minority in all capitals of the former Yugoslavian republics. They make up 2 to 3 percent of the population of Zagreb, Skopje, Ljubljana, and Sarajevo. Another 1.6 million used to live in Bosnia and Herzegovina and 600,000 lived in Croatia prior to the Yugoslav wars, but they have now been largely expelled from the latter.

Serbian culture was largely influenced by the Byzantine Empire starting in the ninth century and throughout much of the Middle Ages. Another source of persistent influence is the Serbian Orthodox Church. However, prior to the Ottoman invasion in the fourteenth century Serbs were strongly influenced by the Catholic Church, especially in the coastal areas such as Montenegro and Croatia. Austrians and Hungarians have also been highly influential among Croatian Serbs, Serbs of Vojvodina, and Bosnian Serbs to a smaller extent. Serbian culture declined during the five-hundred-year rule of the Ottoman Empire. After Serbia became autonomous in 1817, there was a resurgence of Serbian culture that remains strong today in Central Serbia. The Socialist Federal Republic of Yugoslavia, which was formed following World War II and was in existence until the wars of the 1990s, was part of the Soviet Bloc of Communist countries, but in recent decades there has been a growing influence from the West as well as a resurgence in traditional culture.

Serbs have played a major role in world history. In 1914 Gavrilo Princip (1894–1918), a Bosnian Serb, assassinated Archduke Franz Ferdinand (1863–1914), heir to the imperial throne of the Austro-Hungarian Empire. This act precipitated the crisis that would lead to World War I. In more distant history Djordje Petrovic Karadjordje (died 1817) led the 1804 rebellion against the Turks, who were then in power. Serbs have played a significant role in the development of the arts and sciences as well. Prominent Serbs include the scientists Nikola Tesla (a Croatian Serb; 1856–1943), Michael Pupin (1858–1935), Jovan Cvijić, and Milutin Milankovic; the famous composers Stevan Mokranjac and Stevan Hristic; literary authors Ivo Andrić (1892–1975) and Milos Crnjanski; and Vuk Stefanović Karadžić (1787–1864), credited with reforming the Serbian language. Other famous members of the Serbian community are sports stars Vlade Divac, Peda Stojakovic, and Nemanja Vidic; and actor Karl Malden (Mladen Sekulovich). From the entertainment arena there are movie directors such as Dusan Makavejev, Peter Bogdanovich, and Emir Kusturica, and TV producer Paul Stojanovich.

**SERIAL CORRELATION**

Serial correlation is a statistical term that refers to the linear dynamics of a random variable. Economic variables tend to evolve parsimoniously over time and that creates temporal dependence. For instance, as the economy grows, the level of gross national product (GNP) today depends on the level of GNP yesterday; or the present...
inflation rate is a function of the level of inflation in previous periods since it may take some time for the economy to adjust to a new monetary policy.

Consider a time series data set \( \{Y_t, X_{1t}, \ldots, X_{kt}\} \) for \( t = 1, 2, \ldots, T \). Our interest is to estimate a regression model like \( Y_t = \beta_0 + \beta_1 X_{1t} + \ldots, \beta_k X_{kt} + \varepsilon_t \). For instance, \( Y_t \) is the inflation rate, and \( X_{1t}, \ldots, X_{kt} \) is a set of regressors such as unemployment and other macroeconomic variables. Under the classical set of assumptions, the Gauss-Markov theorem holds, and the ordinary least squares (OLS) estimator of the \( \beta_i \)'s is the best, linear, and unbiased estimator (BLUE). Serial correlation is a violation of one of the classical assumptions. Technically, we say that there is serial correlation when the error term is linearly dependent across time, that is, \( \text{cov}(\varepsilon_t, \varepsilon_s) = 0 \) for \( t \neq s \). We also say that the error term is autocorrelated. The covariance is positive when on average positive (negative) errors tend to be followed by positive (negative) errors; and the covariance is negative when positive (negative) errors are followed by negative (positive) errors. In either case, a covariance that is different from zero will happen when the dependent variable \( Y_t \) is correlated over time and the regression model does not include enough lagged dependent variables to account for the serial correlation in \( Y_t \).

The presence of serial correlation invalidates the Gauss-Markov theorem. The OLS estimator can still be unbiased and consistent (large sample property), but it is no longer the best estimator, the minimum variance estimator. More importantly, the OLS standard errors are not correct, and consequently the t-tests and F-tests are invalid.

There are several models that can take into account the serial correlation of \( \varepsilon_t \): the autoregressive model AR(p), that is, \( \varepsilon_t = \rho_1 \varepsilon_{t-1} + \rho_2 \varepsilon_{t-2} + \ldots + \rho_p \varepsilon_{t-p} + \nu_t \), where \( \nu_t \) is now uncorrelated with zero mean and constant variance; the moving average MA(q) \( \varepsilon_t = \theta_1 \nu_{t-1} + \ldots + \theta_q \nu_{t-q} + \nu_t \); or a mixture model ARMA(p,q). Testing for serial correlation in the error term of a regression model amounts to assessing whether the parameters \( \rho_i \)'s and \( \theta_i \)'s are statistically different from zero. A popular model within economics is the AR(1) model: \( \varepsilon_t = \rho_1 \varepsilon_{t-1} + \nu_t \). Within this model, the null hypothesis to test is \( H_0: \rho_1 = 0 \). If we reject the null hypothesis, we conclude that there is serial correlation in the error term. To implement the test, we proceed by running OLS in the regression model. We retrieve the OLS residuals \( \hat{\varepsilon}_t \) and, assuming that the regressors \( X_{1t}, X_{2t}, \ldots, X_{kt} \) are strictly exogenous, we regress \( \hat{\varepsilon}_t \) on \( \hat{\varepsilon}_{t-1} \). A t-statistic for \( H_0: \rho_1 = 0 \) will be asymptotically valid. If the autoregressive model is of a large order, an F-test for a joint hypothesis as \( H_0: \rho_1 = \rho_2 = \ldots = \rho_p = 0 \) will also be valid. If the regressors are not strictly exogenous, the auxiliary regression of \( \hat{\varepsilon}_t \) on \( \hat{\varepsilon}_{t-1} \) should be augmented with the set of regressors \( X_{1t}, X_{2t}, \ldots, X_{kt} \) for the t-test and F-test to be valid. There is also a very popular statistic, the Durbin-Watson, which also requires strict exogeneity that tests for AR(1) serial correlation. The main shortcoming of this test is the difficulty in obtaining its null distribution. Though there are tabulated critical values, the test leads to inconclusive results in many instances.

Once we conclude that there is serial correlation in the error term, we have two ways to proceed depending upon the exogeneity of the regressors. If the regressors are strictly exogenous, we proceed to model the serial correlation and to transform the data accordingly. A regression model based on the transformed data is estimated with generalized least squares (GLS). If the regressors are not exogenous, we proceed to make the OLS standard errors robust against serial correlation. In the first case, let us assume that there is serial correlation of the AR(1) type, that is, \( \varepsilon_t = \rho_1 \varepsilon_{t-1} + \nu_t \). In order to eliminate the serial correlation, we proceed to transform the data by quasi-differencing. For simplicity, suppose that the regression model is \( Y_t = \beta_0 + \beta_1 X_{1t} + \varepsilon_t \). The following transformation will produce a regression model with an uncorrelated error term:

\[
Y_t - \rho_1 Y_{t-1} = \beta_0 (1 - \rho_1) + \beta_1 (X_{1t} - \rho_1 X_{1t-1}) + \varepsilon_t - \rho_1 \varepsilon_{t-1} = \beta_0 (1 - \rho_1) + \beta_1 (X_{1t} - \rho_1 X_{1t-1}) + \nu_t.
\]

If \( \rho_1 \) is known, it is easy to obtain the quasi-differenced data, that is, \( Y_t - \rho_1 Y_{t-1} \) and \( X_t - \rho_1 X_{t-1} \), and proceed to run OLS in the model with the transformed data. This will produce a GLS estimator of the \( \beta_i \)'s that now will be BLUE as the new error term \( \nu_t \) is free of serial correlation. In practice, \( \rho_1 \) is not known and needs to be consistently estimated. The estimate \( \hat{\rho}_1 \) is obtained from the auxiliary regression of \( \hat{\varepsilon}_t \) on \( \hat{\varepsilon}_{t-1} \). We proceed by quasi-differencing the data, \( Y_t - \hat{\rho}_1 Y_{t-1} \) and \( X_t - \hat{\rho}_1 X_{t-1} \), and as before, running OLS with the transformed data. The estimator of the \( \beta_i \)'s now is called the feasible GLS estimator (FGLS), which is a biased estimator, though asymptotically is still consistent. In practice, the FGLS estimator is obtained by iterative procedures known as the Cochrane-Orcutt procedure, which does not consider the first observation, or the Prais-Winsten procedure, which includes the first observation. When the sample size is large, the difference between the two procedures is negligible.

In the second case, when the regressors are not strictly exogenous, we should not apply FGLS estimation because the estimator will not be even consistent. In this instance, we modify the OLS standard errors to make them robust against any form of serial correlation. There is no need to transform the data as we just run OLS with the original data. The formulas for the robust standard errors, which are known as the HAC (heteroscedasticity and autocorrelation consistent) standard errors, are provided by Whitney Newey and Kenneth West (1987). Nowadays, most of the econometric software calculates the HAC standard errors, though the researcher must input the
value of a parameter that controls how much serial correlation should be accounted for. Theoretically, the value of this parameter should grow with the sample size. Newey and West advised researchers to choose the integer part of \(4(T/100)^{2}\) where \(T\) is the sample size. Although by computing the HAC standard errors we avoid the explicit modeling of serial correlation in the error term, it should be said that they could be inefficient, in particular when the serial correlation is strong and the sample size is small.

**Gloria González-Rivera**

**SEROTONIN**

Serotonin, like dopamine and norepinephrine, is a brain neurotransmitter. When the brain produces serotonin, tension is eased and the subject feels less stressed and more focused and relaxed. In contrast, when it produces dopamine or norepinephrine there is alertness in thinking and acting. Serotonin is called the “calming chemical.” It can be obtained naturally by eating sugar or other carbohydrates, which raise the insulin level in the blood, triggering a greater ratio of a chemical (actually, an enzyme) called tryptophan. This in turn rushes to the brain, where it produces serotonin. Vitamin C is required for the conversion of tryptophan into serotonin. Tryptophan is found in foods such as bananas, plums, turkey, and milk. A diet poor in omega-3 fatty acids may lower brain level serotonin and cause depression.

**CHEMICAL COMPOSITION AND ACTION**

Serotonin was isolated and named by Maurice M. Rapport, Arda Green, and Irvine Page in 1948. First, Rapport identified it as a vasoconstrictor substance in the blood serum, and because it is a serum agent that affected vascular tone he called it *serotonin*. Later, in 1950, Rapport identified serotonin chemically and gave it the chemical name 5-hydroxytryptamine. The chemical name of serotonin is \(3-(2\text{-aminoethyl})-1H\text{-indol-5-ol}\), and in pharmacological terminology 5-HT.

The chemical formula of serotonin is \(\text{C}_{10}\text{H}_{12}\text{N}_{2}\text{O}_{2}\). Its molecular mass is 176.2182 g/mol, its monoisotopic mass is 176.0960 g/mol, and its composition is as follows: N (15.8970 percent), O (9.0793 percent), C (68.1598 percent), and H (6.8638 percent).

Specifically, serotonin is a monoamine neurotransmitter that is synthesized in the central nervous system by the serotonergic neurons and in the gastrointestinal tract by the enterochromaffin cells. Serotonin is formed by the hydroxylation and decarboxylation of tryptophan. The greatest concentration of serotonin is found in the enterochromaffin cells of the gastrointestinal tract (90 percent), and the rest is found in platelets and in the central nervous system. The effects of serotonin are mostly felt in the cardiovascular system, with additional effects in the respiratory system and the intestines.

The function of serotonin is exerted upon its interaction with specific receptors. Several serotonin receptors have been cloned, such as 5HT1, 5HT2, 5HT3, 5HT4, 5HT5, 5HT6 and 5HT7. Within each group there are subtypes that affect various aspects of bodily functions.

More specifically, serotonin can be found in the human gastrointestinal tract and in the bloodstream. In the human body, serotonin can be synthesized from the amino acid tryptophan by a short metabolic pathway that consists of two enzymes: tryptophan hydroxylation and amino acid decarboxylase. The first enzyme, tryptophan hydroxylase, has two forms, one that is present in several tissues and the other one in a brain-specific isoform. In contrast, in the central nervous system serotonin can also be synthesized by the neurons of the Raphe nuclei that are distributed along the length of the brainstem in nine pairs. Specifically, there are swellings, called varicosities, along the axon that release serotonin into the extraneuronal space. From there, serotonin can be diffused to activate special receptors that exist on the dendrites, the cell bodies, and the presynaptic terminals of the adjacent neurons.

Serotonin plays an important role in the regulation of mood, sleep, appetite, vomiting, sexuality, memory and learning, temperature regulation, cardiovascular function, and endocrine regulation. Low levels of serotonin have been associated with migraines, bipolar disorders, apathy, fear, feelings of worthlessness, insomnia, fatigue, anxiety, and depression (www.chm.bris.ac.uk/motm/serotonin/depression.htm). Autopsies on suicide cases have revealed very low levels of serotonin in the brain. In turn, low levels of serotonin can be caused by an anxiety disorder because serotonin is required for the metabolism of stress hormones. The most concrete evidence for the connection between serotonin and depression is the decreased concentrations of serotonin in the cerebrospinal fluid and brain tissues of people suffering from depression.
Extremely high levels of serotonin in the body cause toxic effects, and are even fatal in some cases; this is termed "serotonin syndrome."

In 2005 scientific evidence emerged that genetic polymorphisms in the enzyme tryptophan hydroxylase in both its forms can affect susceptibility to depression and anxiety (Nash et al. 2005; Zhang et al. 2005). Furthermore, a study in 2006 showed that ovarian hormones can affect the expression of tryptophan hydroxylase, triggering postnatal depression and premenstrual stress syndrome (Hiroi et al. 2006). Also, where infants have abnormal serotoninergic neurons—those neurons on the brain stem that synthesize serotonin—there is a high possibility of sudden infant death syndrome (SIDS) (Weese-Mayer, et al. 2003). Based on recent research, by Lesur et al. (2006), serotonin mediates liver regeneration and induces cell division throughout the body.

The pharmacology of serotonin is very complex because there is a large and diverse range of serotonin receptors in the human body. At least seven types of such receptors have been identified in different places of the body, and they all have different effects. Serotonin receptors can be stimulated by psychoactive drugs such as ecstasy (MDMA), LSD, DMT, and psilocybin (a substance found in psychedelic mushrooms). A small dose of ecstasy, for example, stimulates a big release of serotonin in the body, causing feelings of well-being, comfort, and tactile sensitivity. High doses of such substances can produce feelings of emotional empathy, or entactogenesis.

The 5-HT3 receptor is an antiemetic agent used mainly in cases of postoperative nausea and nausea caused by anticancer chemotherapy using cytotoxic drugs. It is also used to treat depression and other mental and psychological conditions. The 5-HT 1B/D receptor is an agent to treat migraines. The role of 5-HT receptors is a topic of intense research, so more therapeutic applications may be discovered in the future.

If depression is severe as a result of serotonin deficiency, antidepressants—that is, pharmaceutical agents that increase the level of serotonin in the brain—may be used. If depression is mild, it can be cured without medications because levels of serotonin can be increased with rigorous exercise. Studies have shown that the amount of serotonin in the brain is increased with increased activity, and the production of serotonin is raised for some days after exercise.

TYPES OF SEROTONIN MEDICATIONS
There are certain psychiatric medications that modulate the levels of serotonin in the human body. These have been classified into four general categories: (1) monoamine oxidase inhibitors, (2) tricyclic antidepressants, (3) atypical antipsychotics, and (4) selective serotonin reuptake inhibitors.

Monoamine oxidase inhibitors (MAIOs) are used to prevent the breakdown of monoamine neurotransmitters (one of which is serotonin). Hence, they increase the concentrations of serotonin in the brain. They are used for patients suffering from depression, but they may have serious side effects, including adverse drug interactions such as hypertensive crisis. Tryptic antidepressants (TCAs) inhibit the reuptake of both serotonin and norepinephrine. Selective serotonin reuptake inhibitors (SSRIs) are also used in the treatment of depression. They are newer drugs and inhibit only serotonin's reuptake, hence they are safer, having fewer side effects and fewer adverse drug interactions. One of their side effects is anorgasmia, or a delay of sexual climax.

SSRIs available in the United States (with trade names given in parentheses) include:

- Citalopram (Celexa, Cipramil, Emocal, Sepram, Seropram);
- Escitalopram oxalate (Lexapro, Cipralex, Esertia);
- Fluoxetine (Prozac, Fontex, Seromex, Seronil, Sarafem);
- Fluvoxamine maleate (Luvox, Faverin);
- Paroxetine (Paxil, Seroxat, Aropax, Deroxat, Paroxat);
- Sertraline (Zoloft, Lustral, Serlai);
- Dapoxetine (no known trade name).

SSRIs are prescribed for treatment of major depression, anxiety disorders, panic disorders, obsessive-compulsive disorders (OCD), social phobia, eating disorders, irritable bowel syndrome (IBS), and premature ejaculation (which affects up to 60 percent of men).

Briefly, the mechanism of brain cells is as follows: The messages in the brain are passed between two nerve cells through a synapse, which is a small gap between the cells. The sender (presynaptic) cell releases neurotransmitters such as serotonin, dopamine, and norepinephrine into that gap. These neurotransmitters are recognized by special receptors on the surface of the receiver cell (postsynaptic), which, upon this stimulation, relays the signal. During this process, approximately 10 percent of the neurotransmitters are lost; the remaining 90 percent are released from the receptors to be taken back by monoamine transporters into the sender cell (presynaptic). This process is called “reuptake.” When there is a problem in this operation, some type of disorder appears in the person's behavior.

According to some theories, a lack of stimulation of the receiver cell (a postsynaptic neuron) at a synapse can...
cause depression. In order to stimulate this receiver cell, SSRIs, as their name implies, inhibit the reuptake of serotonin only from the three neurotransmitters. In contrast, TCAs inhibit the reuptake of both serotonin and norepinephrine. When medication is used, serotonin stays in the synaptic gap longer than it normally would so that it can be recognized again by the receptors of the postsynaptic cell and the process can be repeated, thus the postsynaptic cell can finally be stimulated fully, as it should have been originally.

**MEDICATION SIDE EFFECTS**

Adverse effects of SSRIs include general side effects, suicidality, sexual side effects, and “discontinuation syndrome.” Specifically, during the first four weeks of treatment with SSRIs symptoms may include nausea, drowsiness, headache, changes in weight and appetite, changes in sexual behavior, increased feelings of depression and anxiety, tremors, and increased sweating. These symptoms usually disappear after the adaptation period, but they are highly individual and drug-specific.

Regarding suicidality, there have been many accusations by patients and their families that SSRIs cause suicidal ideation and behavior. However, there is little scientific support for these claims, and manufacturers of SSRIs usually have vehemently denied them. But in early 2006 GlaxoSmithKline announced to the media that new meta-analysis of their clinical trial data revealed a statistically significant higher frequency of suicidality in patients treated with their SSRI, paroxetine (Paxil) (GlaxoSmithKline, May 2006, “Clinical Worsening and Suicide Risk,” Press release; www.healthfoundation. healthspace.eu/health/antidepressants-paxil.php).

Regarding the sexual side effects, SSRIs can cause various types of sexual dysfunctions such as anorgasmia, erectile dysfunction, and diminished libido (Laden et al. 2005; Hu Xh et al. 2004). It is believed that sexual dysfunction is caused by an SSRI-induced reduction in dopamine. If the postsynaptic receptors 5-HT2 and 5-HT3 are stimulated, they decrease dopamine release from the Substantia Nigra. Because of these problems, the SSRI fluoxetine (Prozac) was recently classified as a reproductive and developmental toxin by the Center for the Evolution of Risks to Human Reproduction (CERHR), which is an expert panel at the National Institute of Environmental Health Sciences and people were advised to avoid it.

Finally, regarding the discontinuation syndrome, SSRIs have not been found to be addictive. However, a sudden discontinuation of their use may cause both somatic and psychological withdrawal symptoms that collectively are called the “SSRI discontinuation syndrome.” These reactions are different from and usually less significant than the withdrawal symptoms of drugs such as opium, alcohol, or cocaine, but occasionally they have been extreme, and some patients can never withdraw completely from the SSRI drugs. In some cases, stopping the use of SSRIs can cause unpredictable and irregular acts and behaviors (e.g., violent rages, suicidal ideation), as well as an intensification of previous symptoms. In Europe, SSRI products cannot be advertised as “non-habit-forming,” as they are in the United States. According to the World Health Organization, SSRIs meet the definition of “addictive” (Tamam and Ozpoyraz 2002).

Serotonin toxicity, commonly referred to as “serotonin syndrome,” is a toxioid (a form of poisoning) caused by medical treatment. Increased serotonin levels in the central nervous system can result from the use of archetypal serotonergic drugs, examples being the specific or selective serotonin reuptake inhibitors (SSRIs). The toxicity of SSRIs increases with greater dosages, but overdose of an SSRI alone is not fatal in healthy adults. The toxicity can be fatal, however, when drugs with different mechanisms are mixed together. The most common combination of therapeutic drugs likely to raise serotonin to a fatal level is the combination of MAOIs with SSRIs or TCAs (Gillman 2004; Isbister et al. 2004). The duration of an episode of serotonin toxicity depends on the type of drugs that precipitated it. Many of them have durations of less than twenty-four hours, and side effects or toxicity will subside over this time, without specific treatment, if one or all of the offending drugs are reduced or ceased completely. As of the mid-2000s there was no evidence of permanent or long-term neurological effects or damage from serotonin toxicity (Whyte 2004).

In approximate order of seriousness (from least to most serious), the symptoms of serotonin toxicity, according to Dunkley (2003), include:

1. neuromuscular hyperactivity: tremor, clonus, myoclonus, hyperreflexia, and (only in late or severe stage) rigidity, which may effect truncal muscles;
2. altered mental status: excitement, agitation, and (only in late or severe stage) confusion;
3. autonomic hyperactivity: diaphoresis (excessive sweating), fever, mydriasis (eye dilation), tachycardia (elevated heart rate), moderately elevated blood pressure, and tachypnoea (rapid breathing).

The usual clinical picture is of a hypervigilant or agitated patient with tremor and hyperreflexia. Clonus and myoclonus (involuntary muscle contractions) usually begin in lower limbs and may spread and become generalized. Pyramidal rigidity (a rigidity of certain muscles) is a late development (usually it happens when MAOIs have been mixed with SSRIs) and may impair respiration if it affects truncal muscles. Serious toxicity is indicated by...
high rigidity, a fever higher than 38.5 degrees Celsius, and an increasing PaCO2 (arterial carbon dioxide pressures).

BIBLIOGRAPHY

Jones, Brian J., and Thomas P. Blackburn. 2001. The Immune System, Depression, and During the seventeenth, eighteenth, and early nineteenth centuries in the European colonies of the Americas, when almost all productive labor was performed by slaves, and during the seventeenth, eighteenth, and early nineteenth centuries in the European colonies of the Americas, where the majority of workers producing for the market worked under some form of servitude.

SERVITUDE

Servitude is a relationship between two people in which one person, the servant, has to work for the benefit of another person, the master, without the right to quit and seek other employment freely. Typically, the master may sell or give the servant away under some conditions and may be thought of as having a property right in that person. In some cases, the master may be a corporate entity such as a government or business. Normally, the servant receives only basic food, shelter, and clothing from the master, although the servant’s rights to own or receive property vary widely.

Servitude has existed throughout human history, and ancient civilizations organized almost all labor under some type of master-servant relationship. The peak periods for servitude in Western civilization were during the late Roman Republic (late second to mid-first centuries BCE), when almost all productive labor was performed by slaves, and during the seventeenth, eighteenth, and early nineteenth centuries in the European colonies of the Americas, where the majority of workers producing for the market worked under some form of servitude.
The relationship between master and servant is both economic and personal. Masters and servants have an unequal relationship, of course. But this does not prevent masters from seeing servants as social as well as economic assets and taking care of them beyond the minimum required to keep a valuable worker productive. And it does not prevent servants from seeing their masters as patrons as well as employers. These sorts of feudal relationships may be more or less present, depending on a number of variables, including the connection of the plantation or workshop to a wider marketplace; the potential profits to be gained from servants’ labor; whether master and servant live together; whether they share a common language, ethnicity, culture, or religion; and the values taught by their culture and religion.

In addition, there are generally capitalist elements to the master-servant relationship. The servant is also a worker who produces the goods that the master needs. Often the master is a participant in a competitive marketplace where productivity is all-important and the servant has little stake in the master’s success in the market. The balance between feudal and capitalist elements in the master-servant relationship is responsible for many of the differences in servants’ treatment under different forms of servitude.

Servitude and free labor are normally incompatible. Free laborers resent servants and masters because servitude depresses wage rates and because they may feel discriminated against by the feudal relationship to the extent that any exists. For example, working people in the Northern United States in the early nineteenth century opposed slavery in the Southern states not so much because of their belief in universal principles of human rights, but because they feared that the “slave power” of the Southern planters might impair their own freedom. By their response that Southern slaves were treated better than Northern workmen, Southern apologists for slavery actually fed these fears. Rural landholders who are heavily invested in being masters, both in economic terms and as a part of their identity, tend to resist the end of servitude, but the bourgeoisie often see servitude as inefficient and ideologically unsound. Thus servitude tends to change forms or decline as capitalist free labor rises.

Servitude has existed in many forms around the world and in virtually all times and places. Among the forms of servitude are slavery, indenture, debt servitude, serfdom, prison labor, conscription or corvée, and ethnic or lineage servitude.

**SLAVERY**

Slavery is distinguished from other forms of servitude by being lifelong and heritable. In Western traditions, the children of an enslaved woman are usually slaves regardless of the status of the father, although this may not be true in some non-Western slave systems. The slave is the personal property of the master, and that property right can be transferred for cash. Slave systems, like other forms of servitude, have always had legal and customary restrictions on the masters’ right to exploit slaves’ labor, abuse or neglect slaves, or transfer them to another owner. Free people can be enslaved, most commonly as a result of capture in wartime, but also as a legal punishment. Slaves can be freed, or manumitted, by their masters as a reward for service or in return for payment, although there are often legal and customary restrictions to the practice.

One tends to think of slavery as being tied to race, and in the Americas in the early modern period this was certainly the case. Prior to the fifteenth century, however, most slaves in Europe, Asia, and the Middle East were of similar ethnicity to their masters, and this was commonly true of slaves in antiquity. Certainly the equation of slavery and African origins did not exist before the fifteenth century. Having the same or a similar ethnicity and religion as one’s master, however, conferred few or no legal rights enforceable against the master.

Millions of people came from Africa to the Americas, the Middle East, and the Mediterranean as slaves between the fifteenth and nineteenth centuries. The modern African diaspora is mostly the product of the slave trade. In the Islamic world, slaves were commonly employed as personal retainers—household employees, administrators, and soldiers—rather than agricultural laborers. As in the Western world, most Islamic slaves were brutally exploited, but some were able to rise to positions of great power, delegated by their master but no less real. Egypt was ruled by a *junta* of slave soldiers, the Mamluks, for several centuries. The Ottoman Empire was ruled by a sultan but administered by a grand vizier and his assistants, who were the sultan’s slaves.

Most countries abolished slavery in the nineteenth century, and as a legally sanctioned system it is very rare today. Most of what is called slavery in modern times, such as the imprisonment of young women in the sex trade or of workers in sweatshops, is more properly classified as indenture or debt servitude. Slavery in the individual, permanent, heritable sense still exists in a few African and Middle Eastern countries. Slavery is formally outlawed everywhere but is accepted by custom and social practice in Mauretania, Sudan, Yemen, Somalia, and many other areas in the region not under the effective jurisdiction of national governments.

**INDENTURE**

Under indenture, the property right of a master in a servant is transferable but limited in time, and the children of the servant are usually free. The conditions under
which indentured servants work are governed by contract, custom, and sometimes by law. Indenture typically occurs when free people more or less voluntarily agree to indenture themselves for a period of time in exchange for some benefit, usually financial, although they might be tricked or coerced into signing a contract.

Many European immigrants to the Americas in the seventeenth and eighteenth centuries came as indentured servants, having agreed to work for a period of five or seven years in exchange for transportation to America and a small grant of land, livestock, and farm equipment at the end of the contract. Some were prisoners or were forced to accept indenture in order to avoid imprisonment, while others were actually kidnapped off the street; but most signed up willingly enough in order to escape horrible poverty in Europe.

In general, indenture is no longer legal, but it is still quite common. Many people sign employment contracts, and those contracts can legally contain penalties for non-fulfillment, but individuals are not forced to work against their will. Outside the law, however, many illegal migrants from East Asia sign indenture contracts with the smugglers who bring them to the United States, the Middle East, or elsewhere. These contracts are not legal in any country, but they can be enforced by extralegal means by the criminal masters. In some cases, masters have considerable power in local political systems and are able to enforce theoretically illegal contracts using governmental power, so it is harder to claim that indenture has been completely outlawed.

DEBT SERVITUDE
In debt servitude, the master gains a property right over the servant similar to indenture, and that property right can be bought and sold. However, instead of the servitude being limited in time, it lasts until the servant pays off a debt. The master is typically in charge of the accounting so this may take quite a while. In some systems, the debt is heritable, as is the servant status. This is called peonage.

In Spanish America after the collapse of the encomienda system (a sort of ethnic servitude) in the sixteenth century, wealthy landowners ensured a steady supply of farm labor by forcing the local peasants to peonage. The peons were required to buy their goods at the landowner’s store and were paid in scrip that could only be exchanged there. They were encouraged to borrow against the value of the coming year’s crop, and inevitably found their debt, and thus their labor obligation, increasing year by year.

A modern form of debt servitude is common in the sex industry. Young rural women are sold by their parents in order to satisfy a debt and find themselves working in brothels until the creditor is satisfied. This frequently lasts until age or disease makes the woman unfit for profitable work in prostitution.

As in indenture, the limited nature of debt servitude tends to weaken the feudal ties between master and servant. Masters generally have little compunction about "releasing" servants who become unprofitable, often leaving them destitute. No country’s laws permit debt peonage today, but influential masters often get the support of local officials and criminals are able to enforce debt servitude without benefit of police power.

SERFDOM
Serfs were servants tied to the land under a feudal system. Serfs worked for the owner of the land under conditions typically fairly tightly regulated by law and tradition. A wide variety of rules applied, but typically the master could call upon a serf to perform a specific set of tasks (tend a certain field, for example) or provide a certain amount of labor (so many days or so many hours a day, for example) during the agricultural cycle. The serf could not be bought or sold without the land to which he or she was attached. Medieval peasant villages often provided much of their own government, but the master-serf relationship generally gave the master some sort of legal jurisdiction as well as a right to labor service, and the serf gained some right to protection, support in illness and old age, and other social services from his or her master. The serfs’ traditional rights to use the soil as they saw fit often kept landowners from developing their land, and the abolition of serfdom proved advantageous to progressive landlords in the early modern period, if not to the serfs themselves.

In seventeenth-century Russia, on the other hand, masters gained the right to transfer serfs fairly easily from one piece of land to another in response to the rapid expansion of agriculture into eastern lands captured from nomadic peoples. Subsequently, by a legal fiction, serfs could be transferred from one master to another without a transfer of land, and the condition of the Russian serf became similar to that of a slave, subject to being bought and sold as an individual. In medieval Western Europe, on the other hand, serfs had stability in their villages and could be locally influential farmers with considerable wealth and security.

No country permits serfdom today, and relationships of this type are rare.

PRISON LABOR
In a prison labor system, property rights to servants are owned not by an individual but by the government. Governments might exercise this right directly or transfer it to a private party in return for rent. The servitude is a
punishment for a real or pretended crime, is limited in time by the prisoner’s sentence, and is not heritable.

In nineteenth-century Australia, much of the productive labor was performed by prisoners, whose labor was leased by free settlers. Free laborers resented prison labor, though, as it drove down wages and discouraged free migration, so as each state’s economy matured, it stopped accepting transported prisoners. In the American South in the aftermath of the Civil War, imprisonment was a tool of social control over the newly freed black population. Landowners rented prisoners’ labor, which helped defray the cost of the huge prison systems. Other prisoners worked on chain gangs to build new infrastructure or produce products the state needed. In Stalinist Russia, prisoners performed much of the labor used to develop the Siberian industrial plants, which produced the weapons that helped win World War II.

Prison labor is very common today. The United States has laws against the importation or transport across state lines of products made by prisoners, but states still use prison labor for many items used by their governments, the most famous being license plates. Chinese factories sometimes contract with the prison system for labor, although this must be concealed if the products are to be exported.

CONSCRIPTION OR CORVÉE

In conscription or corvée systems, free individuals are required to work for their government for a certain period of time as a condition of citizenship or residence. Conscription generally refers to military service, while corvée implies forced civilian service, often as labor on infrastructure projects. The service is generally limited in time, either for the duration of a conflict or for a certain fixed period.

Conscription reached its height in the age of mass armies in the first half of the twentieth century. Millions of conscripts, often serving very much against their will, fought on all sides of the world wars of that period. Conscription into the British navy during the seventeenth and eighteenth century was less organized, accomplished by press-gangs of sailors who would literally kidnap men and force them onto ships, where they would serve for years.

Corvée labor was a feature of colonial practice during the second great wave of European colonialism in the nineteenth century. The most notorious example is the forced recruitment of rubber collectors in the Belgian Congo. Workers’ families would be kidnapped and raped or beaten if the worker ran away, and if workers didn’t bring in enough product, their hands might be cut off by colonial soldiers. Nazi Germany also used corvée labor in which civilians taken from occupied territories were used to supplement prison labor in the arms industry.

Conscription is still very common today. Many countries consider military service obligations to be a part of civic education for their citizens. Corvée labor is still found in many developing countries on a limited scale, often used for road repair or urban beautification campaigns.

ETHNIC OR LINEAGE SERVITUDE

As with prison labor and conscription, in ethnic or lineage servitude the owner is a group: an ethnic group, a powerful family, or a government. The servants generally owe their labor collectively as well. A particular ethnic group, defeated nation, family, village, or other collective entity will be required to furnish a certain amount of labor to their masters under conditions set by custom or law.

The best-known example of this in European-controlled territories is the encomienda system in Spanish America during the colonial era. After the Spanish conquest, the defeated native peoples were required to pay tribute in the form of products and labor: so many bushels of corn and so many men for such an amount of time from each village. The government used some of the labor on its own infrastructure projects, to build cathedrals, fortifications, viceroy’s palaces, and the like. Most labor service, though, was assigned to Spanish conquistadors on a temporary basis, not as a property right but as a payment for the masters’ service to the state. Spanish masters might employ the laborers on their own land as agricultural workers, and the situation of the indigenous people in some cases approached that of serfs under Western European feudalism. Many encomienda Indians were sent to work in mines, where they were brutally exploited. The encomienda system deteriorated as the native population declined through the fifteenth century. Indians could also escape the encomienda system by leaving their villages and moving to the cities or living on lands owned by Europeans, who would employ them as wage laborers or peons.

Lineage slavery was prevalent in west Africa, as, for example, among the Fulani of Guinea. After the conquest of the Fouta Djallon highlands in the seventeenth century, the defeated peoples were adopted into Fulani clans but given distinctive surnames. The members of the “slave” lineage groups were given land to plant crops on, while the descendents of the conquerors continued their pastoral lifestyle. The obligation of farmers to pay in-kind tribute and labor service to herders continued under French colonial rule, but was abolished after independence. The sense of status remains, however, governing marriage choice, leadership within communities, and patron-client relationships, even though as servitude the system has ended.

THE AFTERMATH OF SERVITUDE

It is common for all forms of servitude to have lingering repercussions. Individuals can escape servitude, either at
the end of their term of service, by flight, or by manumission. Whole populations can escape through changes in laws and customs. But even a profound social revolution cannot erase the cultural memories of servitude, which continue to affect relationships between the descendants of masters and the descendants of servants for many generations. When mixed with racial differences, as can be seen in the United States in the twenty-first century, this can produce poisonous social dysfunction.

Sometimes, however, the aftermath is more positive. In the Roman Empire after the first century CE, for example, as the tide of conquest stopped and, with it, the flow of new slaves dried up, the gradual manumission of most slaves led to the establishment of a fairly benign system of patron-client relationships between patricians and the descendents of their freedmen. This patronage system formed the basis for the remarkable strength of Roman culture even after the barbarian invasions starting in the fourth century CE.

SETTING, PRICE

SEE Price Setting and Price Taking.

SETTLEMENT

The term *settlement* has a number of meanings attributed respectively to the areas of law, finance, archaeology, and history. The legal definition generally refers to the act of settling a dispute or disagreement and reaching an agreement on the case, which then settles the claim. Often both sides of a lawsuit have a strong incentive to settle, chiefly to avoid costs. Courts can enforce settlements, and the party in default can be sued for breach of contract. In modern litigation, most suits are either withdrawn or settled, and settlements have become an important feature of the legal process. In rarer instances, the process of giving real estate, land, or some other heritage to someone is called a settlement, as is the respective document.

In finance the term generally describes the settling or payment of an account. More specifically, a settlement delivers securities or interests in securities to fulfill contractual obligations. This is usually preceded by trading and involves a purchase price. Before the introduction of the electronic settlement system in the 1990s, securities settlement was associated with a certain financial risk because it involved the physical movement of paper instruments, which were relatively easy to steal or forge. The transition from paper-based to electronic settlement is accomplished by immobilization, which means that securities are held by depositaries that are electronically linked to a settlement system. The ultimate goal is to dispense with paper instruments entirely (dematerialization).

The term *settlement* is also used to describe a specific human habitat that may include all sizes of human settlements, from hamlets to cities. More specifically, a settlement is the most rudimentary form of human habitation in a formerly uninhabited area. The term also refers to archaeological sites of human habitation. Settlement patterns and landscape approaches, which record material traces of human habitation, have become central for contemporary archaeology because they help explain long-term cultural and behavioral change. Thus archaeologists believe that the first European settlement in North America occurred around 1000 CE, when Viking explorers made their way to Vinland, which is probably modern Newfoundland.

For reasons unknown, European contact with the North American continent was interrupted until the sixteenth century, when the Spaniards reached Florida. In 1565 the Spaniards established the first permanent European settlement at Saint Augustine, a base for missionaries and (slave) traders. A few decades later rival European powers founded settlements along the east coast of the continent. Around 1600 the French assumed control over the Saint Lawrence Valley, founded the settlements of Quebec (1608) and Montreal (1642), and
during the century succeeded in bringing a few hundred settlers to Louisiana. While the Dutch controlled the Hudson River valley for much of the seventeenth century, the major settlements of the English Crown were established in Jamestown (1607) and Plymouth (1620). At the same time the Spanish also started to settle in the Southwest of the continent; however, it took them over 150 years to establish outposts on the coast of the Pacific.

In the Southwest and West the Spanish eventually yielded to American settlers who claimed the territory during the nineteenth century, a claim that not only involved land but also expressed a belief in individual liberty and economic opportunity. The settlement of the West was hastened by the Homestead Act of 1862, which granted 160 acres to any family that lived on the land for five years. In the American West a small village or collection of houses was called a settlement.

In the antebellum South, the term settlement sometimes referred to the living quarters of the slaves on a plantation. In urban areas of the United States, the word settlement acquired a different meaning. The term social settlement originated in London’s East End, where Samuel Barnett and a group of Oxford students founded Toynbee Hall in 1884 by “settling” in a working-class area, not only to help their neighbors but to learn firsthand about the mounting problems of urbanization. Only two years later the first settlement house was founded in the United States, and the settlement movement grew rapidly, with Hull-House in Chicago, College Settlement in New York, and South End House in Boston becoming the most famous social settlements. Because settlements mainly worked for and among ethnically diverse urban populations, they became central to the reform efforts of the Progressive Era. The settlement idea also spread to western Europe, South Asia, and Japan; and the International Federation of Settlements and Neighborhood Centres was founded in 1926 as a worldwide association of national, regional, and local organizations working to strengthen communities in society.

SETTLEMENT, NEGOTIATED

A settlement is a contract between two or more parties to resolve a legal dispute without a trial. Most civil cases are decided by settlement, and the contract usually incorporates the desire of the parties to give up their legal claims against one another in return for certain conditions written into the settlement agreement. When a settlement agreement is reached, it is usually submitted to the court with jurisdiction over the dispute in the form of a joint stipulation by the parties to be incorporated into an order. In suits where the plaintiff’s claims have been satisfied by the payment of money, the plaintiff can simply file a notice with the court that the case has been dismissed.

Because litigation is expensive and parties may not have the financial resources to afford protracted legal proceedings, settlement is encouraged. A court may request, or order, the parties to a dispute to participate in a settlement conference or mediation to attempt to resolve their dispute before a trial is held. A mediation or settlement conference provides the parties with an opportunity to resolve their differences without a costly and time-consuming trial. Settlement talks also reduce the risks associated with a trial. In many cases, settlement negotiations lead to a more favorable outcome for the parties than a trial because the parties retain more control over the process. Courts tend to favor settlement negotiations as a way to promote judicial efficiency and reduce the backlog of cases on the docket.

In the interest of facilitating settlement, the law treats settlement discussions as confidential and the substance of such discussions as inadmissible at trial and other proceedings. In highly sensitive cases, if a settlement agreement is achieved, the agreement may require the parties to keep its contents confidential. It is important to note, however, that confidentiality is not possible in class action cases in the United States. Pursuant to Rule 23 of the Federal Rules of Civil Procedure and complementary state court rules, all settlements are subject to approval by the courts, and notice to be bound by a settlement must be

Anja Schüler

directed to all class members. Class action lawsuits are more likely to be resolved by a negotiated settlement given the number of parties and the scale of the potential damages involved. Other types of lawsuits that tend to result in settlement include personal injury lawsuits and product liability actions.

Courts will enforce a settlement in the same way they enforce other valid contracts. If a party breaches a settlement agreement, that party can be sued for breach of contract. In some jurisdictions, the original civil action can be revived if a party breaches the settlement agreement.

Settlements are exclusive to civil cases. In criminal proceedings, a prosecutor and defendant may enter into a plea bargain prior to trial. Similar to the class action context in civil proceedings, the judge in a criminal proceeding must approve the plea bargain reached by the parties.

SETTLEMENT, TOBACCO

From 1954 to 2006 three separate waves of civil litigation in the United States occurred against the tobacco industry based on claims of severe health problems associated with tobacco use. Tobacco industry corporations sued during this period included Philip Morris, R. J. Reynolds, Brown and Williamson, American Tobacco, United States Tobacco, British American Tobacco, Lorillard, and the Liggett Group. Also sued during this period were tobacco industry-affiliated organizations including the Tobacco Institute, Center for Indoor Air Research, and Council for Tobacco Research. All three of these affiliated organizations became defunct in 1999 due to the 1998 Master Settlement Agreement signed by the tobacco industry and attorneys general from forty-six states.

THREE WAVES OF TOBACCO LITIGATION

From 1954 to 1978 the first wave of 125 individual personal injury lawsuits mostly related to lung cancer were filed against the tobacco industry based on the legal theories of negligence, misrepresentation, and breach of warranty. The tobacco industry argued in its defense that there was no proven connection between smoking and disease. Few of these cases went to trial and none were decided against the tobacco industry.

From 1979 to 1993 a second wave of about two hundred individual personal injury lawsuits were filed against the tobacco industry using the legal theories of negligence, misrepresentation, breach of warranty, breach of product liability, and negligent failure to inform. In 1964 after the United States surgeon general’s landmark report linked smoking to lung cancer, the tobacco industry continued to maintain in litigation that while there was no proven link between smoking and disease, smokers also assumed the risk when using tobacco due to health warning labels on cigarette packs. Cigarette warning labels were mandated by the federal Cigarette Labeling and Advertising Act of 1965.

Only eighteen of these cases were litigated with only one case filed in 1983 in New Jersey, *Cipollone v. Liggett Group, Inc.*, decided against Liggett Tobacco Company. In 1985 a jury awarded $400,000 to Tony Cipollone, the husband of the original plaintiff Rose Cipollone who had previously died of cancer. This decision was partially overturned when in 1992 the United States Supreme Court ruled there was no liability due to failure to warn of health dangers because of federal cigarette pack warning labels. The United States Supreme Court sent the case back to the New Jersey federal court to rule on the remaining legal claims. However, due to the expense of further litigation the plaintiff dismissed the lawsuit.

In the third wave of cases from 1994 to 2006, several individual and private class action lawsuits primarily in California, Florida, Oregon, Kansas, and Puerto Rico were decided against the tobacco industry using legal theories of torts, fraud, conspiracy, misrepresentation, breach of warranty, breach of product liability, and negligent failure to inform. Legal theories used in state class action cases included using statistics to ascertain if a percentage of Medicaid smokers suffered from disease due to smoking and violation of state tort, consumer protection, antitrust, and racketeering laws. This theory was used to make it easier to sue and win. It was much more difficult to win arguing direct causation between tobacco use and a disease and death. Statistical trends represent an easier form of proof.

The first important private class action lawsuit was *Castano v. American Tobacco* filed in federal court by sixty
plaintiffs’ law firms on May 9, 1994, on behalf of all nicotine addicted individuals. While the class was certified by federal district Judge Okla Jones on February 17, 1995, this class was later decertified on May 23, 1996, by the U.S. Fifth Circuit Court of Appeals. The court ruled this class certification was inappropriate because there were too many differences in the plaintiffs’ claims and wide differences in state laws making the case unmanageable. This decision initiated several new private and state class action lawsuits. The first state lawsuit was filed by Mississippi in 1994 followed by Florida, Texas, and Minnesota. Florida and Mississippi settled in 1997 and Texas and Minnesota settled in 1998 for a combined total of $40 billion allocated over twenty-five years adjusted for inflation and no spending restrictions.

In 1998 the Master Settlement Agreement with the other forty-six states was signed. Payments of $206 billion over twenty-five years adjusted for inflation were awarded to the states. Due to the lack of spending restrictions in the settlement, most states by 2006 had not provided minimal funding for state anti-tobacco programs as defined by best practices by the Centers for Disease Control and Prevention. These state anti-tobacco programs were to include community programs, school programs, youth enforcement, counter-marketing, cessation, and state anti-tobacco education programs.

2006 FEDERAL COURT DECISION
In the federal district court case of United States of America v. Philip Morris USA Inc., et al. filed by the United States Justice Department in 1999 and decided in 2006, Judge Gladys Kessler ruled that the tobacco industry’s fundamental defense in litigation from 1954 to 2006 was a purported claim of insufficient evidence linking smoking to disease. Internally, however, the tobacco industry long acknowledged that cigarettes were harmful and also addictive.

Judge Kessler also ruled that those in the tobacco industry were racketeers as defined under the federal Racketeering Influenced and Corrupt Organizations Act. The court decision also ordered the tobacco industry to permanently refrain from making misleading statements regarding the health and safety of cigarettes and to make public corrective statements on the dangers of cigarette addictiveness and the serious health effects of smoking and secondhand tobacco smoke. This ruling was appealed by the tobacco industry and will be reviewed by a higher court.

EVOLUTION OF LEGAL FINDINGS
While the tobacco industry was highly successful in the first two waves of litigation that were filed from 1954 to 1994 on behalf of individual plaintiffs, the third wave of litigation from 1994 to 2006 represented a dramatic reversal of legal fortune for the industry. This reversal of legal fortune has been due to the advent of new legal theories including state Medicaid reimbursement and revelations of significant industry misconduct revealed in previously secret industry tobacco documents.

SEX, INTERRACIAL
Public disapproval of and legal restrictions on interracial sex, or racial exogamy, have varied widely in civilization, but sex between members of different racial groups has remained common whenever people of different races have lived together. Attitudes toward interracial relationships have evolved since the Age of Discovery and are connected with trends in society, culture, politics, and economics.
THE SIXTEENTH AND SEVENTEENTH CENTURIES
The few people of color in England and in the English colonies in the late sixteenth century and early seventeenth century seemed to have been able to have white sexual and marital partners without great difficulty. Famously, John Rolfe (not Captain John Smith) married Pocahontas and brought her back to England to live with him in the 1630s. In other European countries at the time, interracial sexual relationships, both informal and sanctified by marriage, were not uncommon. In Spain and Portugal there was a long tradition of mestizaje, or race mixing, between whites, Moors (including people from black Africa), and Jews. These relationships were completely unremarkable until after 1492, when increasing restrictions on “New Christians” meant that those in mixed relationships and their mestizo children had a social handicap to overcome. Also after 1492 Spaniards and Portuguese began to have relations with Indians and Africans in the New World, and the mestizos who resulted from these unions often rose to high ranks in their colonial societies. Limpieza de sangre, or purity of blood, was an officially defined characteristic that could be purchased by someone whose ancestry was actually partly Indian or African. Nonetheless, mixed ancestry was a handicap for the children of the conquistadores and their Indian partners.

THE EIGHTEENTH AND NINTEENTH CENTURIES
From being somewhat unusual, culturally exotic, and a slight handicap for the resulting children in the sixteenth century, interracial sex and marriage became taboo (although still enthusiastically practiced) by the nineteenth century. White indentured servant women in Virginia in the eighteenth century who had children of color found their own indentures extended and sometimes their children sold into slavery despite the general legal provision that children follow the free or slave status of the mother. Thomas Jefferson’s long-lasting relationship with his slave Sally Hemings was potent political ammunition for his opponents. Federalist newspapers at the time brought up the rumored relationship, and the situation was somewhat less difficult for those white men who were involved in long-term sexual relationships with women of color. Men who wished to marry women of color generally had to give up some of their civil rights, and those in acknowledged long-term relationships could suffer in social regard and economic relationships with other whites. Men of color who had sexual relations with white women anywhere in the Americas were in great peril—the penalty could be death or, at a minimum, brutal physical punishment and sale to a faraway master. Outside the United States, white men who had informal sexual relations with women of color (as opposed to seeking marriage with them) faced few penalties in social regard and none at all under law. This led to a situation of considerable license, of which some men took enthusiastic advantage.

The traditional interpretation of interracial sex between whites and African American slaves (and between Spanish conquistadores and Indian women) is that these were rapes. Much recent research suggests that most children of mixed race in the slave societies of the Americas were the product of lasting relationships that produced a number of children. Often these relationships were between poor white men and slave or Indian women they worked or lived alongside, as, for example, that between Toussaint Charbonneau and Sacagawea from around 1800 until her death after 1810. It is unclear what inducements led the women to join and remain with their partners. However, in slave societies, although the children of a slave woman and a free man were born slaves, they had a much greater chance of gaining their freedom than did the children of two slaves. And the social price paid by a poor white man for being in an interracial relationship would be less than that paid by a wealthy planter such as Jefferson. Moreover, the price a slave owner or hacendado paid for regularly raping his slaves or peons was unrest in his workforce, and by the beginning of the nineteenth century there was a price paid in social regard in white society, especially in North America. Indeed the most notorious rake, Thomas Thistlewood of Jamaica, had numerous run-ins with his neighbors because of his general brutality toward slaves.

THE TWENTIETH CENTURY
After the abolition of slavery, restrictions on interracial sex became even more pronounced in most former slave societies in the Americas. These prejudices began to
strengthen even in places where there had been few or no slaves, such as in the northern states of the United States and in Britain and France. In former slave societies an ideology of white solidarity, reinforced by legal segregation, meant that even relationships between poor white men and women of color became less common. In contrast, in areas where there were many native people, such as Mexico and the Andean region of South America, informal relations between the races had always been common, but mixed marriages became more common and tolerated after independence from Spain. In Latin America there was a racial hierarchy, but sexual relationships and marriages between people from different levels of the hierarchy were not harshly punished. In the United States, though, by the early twentieth century antimiscegenation laws were common, affecting all interracial relations, not just those between blacks and whites. These laws remained in force until 1967, when they were ruled unconstitutional by the U.S. Supreme Court in *Loving v. Virginia*. Germany adopted harsh miscegenation laws under National Socialism (Nazism). South Africa had miscegenation laws under apartheid, and Israel in the early twenty-first century does not recognize marriage between Jews and non-Jews, although there is no attempt to hinder informal interracial sex. In other areas there have been no laws against mixed marriages or informal relationships, but in many places people in such relationships and their children have faced significant social handicaps, including active interference by the state in child rearing, as in Australia, where children of mixed native and white ancestry were routinely taken away from their parents by the state and raised in orphanages until the 1970s. Informal restrictions and bureaucratic impediments to interracial sex have been much more pervasive and long-lasting than formal laws. In many places in the U.S. South and in the former slave societies of the Americas until the middle of the twentieth century, a man of color could be beaten or killed with impunity for having or even suggesting sex with a white woman. "Quadroon balls" in southern cities functioned to pair white men with women of color, but men sought to conceal their participation, and overt relationships with women of color had grave social consequences.

In the early twenty-first century throughout Europe and North America, men of color who are in sexual relationships with white women continue to suffer social penalties from both whites and fellow members of their minority group. Although white men in these societies often seek out women of color for casual sex—taking advantage of still-extant racial power differentials—more formal relationships invite some social consequences. Mixed-race couples in the United States still report cases of housing discrimination at higher rates than same-race minority families. The most serious prejudice in this regard is against relationships between blacks and whites—exogamy between whites and other racial groups is somewhat better tolerated by both those groups and white society. However, even exogamy between groups that are traditionally the targets of racial discrimination—as between blacks and Latinos or Asians in the United States—has attracted opponents within those groups.

However, restrictions on interracial sex and marriage are much weaker in the early twenty-first century than they were even in the mid-twentieth century. Popular culture bears witness, with interracial couples in movies and television not raising any eyebrows, and powerful people have successful political careers while married to members of other races (for instance, Clarence Thomas, associate justice of the U.S. Supreme Court).

**EXPLANATIONS**

The traditional explanation for prohibitions on exogamy is that people naturally fear the unfamiliar and find it distasteful. This begs the question of why many men from dominant groups in racially mixed societies often seek out women of other races for informal sex. Of course in some cases, as in sixteenth-century Mexico, there were few white women available, but even when there are many white women, white men often seek out women of color for at least informal relationships. Sociobiologists such as Jared Diamond (The Third Chimpanzee) argue that men seek to control sexual access to women they control—members of their own group—while undermining such attempts by males of other groups, thus providing a neat explanation for both restrictions on interracial sex and informal white male exogamy. The problem with sociobiological explanations is that human genetics changes slowly, whereas popular resistance to racial exogamy in Europe and North America has waxed and waned during the last five hundred years, a blink of the eye in evolutionary terms.

Much of the explanation for popular opposition to racial exogamy must lie in the realms of socioeconomic, cultural, and ideological changes. In the area of ideology, Christian religious teaching in the 1400s held that human beings had a single origin—as children of Adam and Eve. All people were human and fully eligible for all the sacraments, including marriage. Reformation thinkers did not deny this scriptural analysis, but the period saw the establishment of national churches in Protestant Europe, and membership in the national church meant citizenship. Inasmuch as slave owners and colonial masters were reluctant to grant the rights of citizenship to their racial subordinates, they also were reluctant to think of them as fellow Christians and marriagable. In any case, the Enlightenment reduced the influence of Christian teaching over Europeans and also raised the possibility that the
Sex and Mating

various races had separate origins. Eighteenth- and nineteenth-century racial ideologies tended to dehumanize the racial other and encouraged whites to preserve racial distinctions in all things, including sex and marriage. The high point of this ideological current was in the early twentieth century, when a harsh racial climate, given scientific sanction by the eugenic movement, spurred the adoption of antimiscegenation laws in most states in the United States that did not already have them. The Virginia law overturned by Loving, for example, was enacted in 1924 and specifically cited eugenics as one of its motivations. There had been miscegenation laws on the books in a number of states in the South before the Civil War, but all such laws in former Confederate states were wiped off the books during Reconstruction. (Maryland was an exception since it remained loyal during the Civil War and was not “reconstructed.”) When the laws returned in the period of Jim Crow, they generally used eugenic arguments. The eventual failure of these laws is a signpost of the generalized decline in the power of racist ideologies in the late twentieth century.

Larger historical forces also had an impact on public attitudes toward interracial sex. At the end of the fifteenth century Europeans had little contact with the racial other outside of Iberia, and it was precisely in Spain and Portugal where there were some restrictions on interracial sex. Those few non-Europeans who lived outside of Spain and Portugal had no difficulty selecting partners of other races. As Europe spread its economic and political control over the entire globe, Europeans felt a need for racial solidarity in the face of much more numerous subject peoples. Support for racial endogamy can be seen as part of a package of ideological responses to the problems presented by colonialism. One strong argument for this point of view is that restrictions on interracial sex and marriage were strongest in those places where Europeans (or their descendants born in the Americas) ruled over large numbers of non-European peoples: in Spanish and Portuguese America in the sixteenth and seventeenth centuries and in the United States and South Africa in the late eighteenth century, the nineteenth century, and the early twentieth century. As non-Europeans gained political power in the late twentieth century, these restrictions began to diminish. However, this explanation does not account for the persistence of popular resistance to racial exogamy or for the opposition among groups traditionally the subject of racial discrimination.

SEX AND MATING

Humans in all cultures engage in various forms of mating, including marriage or committed pair-bonding as well as short-term, casual sexual relationships. Given that reproduction is at the heart of natural selection, decisions about mating are of central adaptive significance. Accordingly, mating is one of the most heavily studied areas in the biological and social sciences. Recent theoretical and empirical findings in human mating research have identified key sex differences in mate preferences, as well as neural and hormonal correlates of mating.

ENTERING RELATIONSHIPS AND THE TRAITS THAT ARE VALUED

Mate preferences may be separated into broad questions of “whether and what” (Li and Kenrick 2006). For long-term relationships, the sexes tend to be equally careful about whether to enter. When considering minimum requirements for a marriage partner, both sexes have equally high standards. However, men tend to be more eager than women to enter short-term sexual relationships, and report significantly lower standards for them, especially for one-night stands. When approached by an opposite-sex stranger who immediately makes an invitation for casual sex, 75 percent of men said yes whereas 100 percent of women said no.

To explain men’s lower short-term mating thresholds and mate preferences in general, at least two major theories have been proposed. Though often presented as competing explanations and hotly debated, sociocultural and evolutionary theories may be compatible in that the former focuses on more immediate, proximate causations, whereas the latter looks to more distal, ultimate explanations. Sociocultural theories explain sex differences by looking to social norms and the influence of larger groups. According to this view (Eagly and Wood 1999), societal
norms tend to influence men to be more agentic and women to be more passive across many endeavors, including sexual behaviors. Thus, the difference in willingness to enter short-term relationships may be due to gender role differences, whereby men are socialized to be sexually autonomous and women are socialized to be sexually restrained.

According to evolutionary theorists (Buss and Schmitt 1993; Gangestad and Simpson 2000), mating psychologies may have developed in response to specific adaptive issues that long- and short-term mating pose to women and men. Men's eagerness for sex can be traced back to differences in minimum obligatory parental investment. Whereas men are physiologically required to contribute only a few sex cells to offspring, women must provide substantial pre- and postnatal resources if offspring are to survive. Because offspring present much higher potential costs to women if they are the results of uncommitted sex, short-term relationships are reproductively less favorable for women than for men. For long-term relationships such as marriage, both sexes invest substantially in the relationship and in raising children, so both sexes may have evolved to be selective about taking on a long-term partner.

Given that a relationship will occur, an equally important consideration concerns what characteristics are valued. When considering long-term mates, men not only value physical attractiveness more than women do, but they also prioritize finding a minimum level of physical attractiveness in their partners. Women value social status more than men do, and women prioritize obtaining a minimum level of social status in long-term mates. Beyond satisfying these priorities, both sexes favor other characteristics such as kindness and intelligence, and ideally prefer a well-rounded mate. For short-term mates, both sexes tend to prioritize having a certain level of physical attractiveness before being concerned about other characteristics.

From a sociocultural perspective, women have less access to status, power, and economic resources than men do. To achieve upward mobility, women place relatively greater emphasis on status-related traits in their marriage partners. However, if the intended mating duration is short-term, then economic constraints should be less relevant and both sexes should be free to prioritize the physical attributes of their potential short-term mates, as men do for long-term mates.

Why is physical appearance prioritized over other desirable traits? Because of time constraints and variation in women's reproductive capacity, ancestral men may have had a need to first and foremost identify long- and short-term partners who were healthy and fertile. Accordingly, men are inclined to place initial value on physical features that signal youth, sexual maturity, and fecundity. However, other characteristics are also important for long-term relationships, and once a moderate amount of physical attractiveness has been verified, more attention is paid to other desirable characteristics.

In contrast to female fertility, male fertility remains relatively constant over the life span. However, men vary in their ability to provide resources for offspring. Because ancestral men who were higher in status had better access to resources, women may have evolved to prioritize social status in long-term mates to ensure essential resources for offspring. For short-term mates, resources are less relevant, and women may value physical attractiveness in response to the adaptive issue of identifying partners with desirable heritable characteristics.

According to this "good genes" theory (Gangestad and Simpson 2000), pathogens encountered during development can lead to visible deviations from bilateral symmetry. A healthy set of genes and immune system allow a person to resist such pathogens. Because testosterone suppresses the immune system, those who simultaneously exhibit testosterone-rich features and bilateral symmetry effectively advertise having genes that are resistant to local pathogens. That is, only those with desirable good genes can afford to be loaded with potentially damaging testosterone and remain symmetrical in appearance. Indeed, male symmetry is correlated with testosterone-mediated secondary sexual characteristics such as masculinity and masculinity, and men whom women consider physically attractive exhibit more facial masculinity and bilateral symmetry. Symmetrical men are more desirable as short-term affair partners and have more sexual partners than asymmetrical men. In ancestral environments, women who mated with physically attractive men may have accrued reproductive benefits by passing on good genes to offspring.

PHYSIOLOGICAL MECHANISMS INVOLVED IN MATE CHOICE

For humans and other biparental species, trade-offs exist between parenting and mating, and individual hormonal profiles likely mediate both male and female reproductive strategies along these lines (Clutton-Brock 1991). In order for conception to occur during a woman's menstrual cycle, a set of hormonal conditions must be present. First, a mid-cycle rise in luteinizing hormone must occur, signaling impending egg maturation. Second, the ovarian hormones estradiol and progesterone must be at optimal levels, with estradiol rising prior to ovulation and progesterone hitting peak levels after ovulation has occurred. Natural selection may have shaped women's mating psychologies to parallel such changes in physiology.
For females, it would be reproductively ideal to find mates who can provide both material and genetic benefits to offspring; however, obtaining both sets of features in one male is difficult. Therefore, most women may need to make strategic trade-offs by selecting long-term partners who are higher in investment potential than sexual attractiveness. Moreover, these trade-offs may have selected for a dual-mating psychology in which women seek primary partners who provide investment while obtaining better genes through extra-pair mating (i.e., mating with individuals other than one’s primary partner).

Indeed, around ovulation, female sexual desire becomes stronger and the number of sexual fantasies increases. However, these are directed not toward primary partners, but toward potential affair partners. This is particularly true if the primary partner is less physically attractive and lacks indicators of genetic fitness, including strength, social dominance, and symmetry. When near ovulation, women prefer masculine and symmetrical faces in men, and the scent of symmetrical men. For women who are in a steady relationship, in-pair sex tends to occur consistently across the cycle, whereas extra-pair sex occurs significantly more often on high-fertility days.

Males also face strategic trade-offs involving differential allocation of effort to mating or parenting. The resolution of these trade-offs depends on cues from the environment. Men tend to allocate more effort to mating to the extent to which they possess indicators of good genotypic quality. When men do not have the attributes that make them attractive to females, or otherwise face limited sexual opportunities, they tend to invest more heavily in a single mate’s offspring. For example, African tribal evidence shows that men of high status have more wives and spend less time on parenting than men of low status.

Testosterone is a steroid hormone that plays a key role in mediating trade-offs in male mating strategies. Higher testosterone levels are associated with greater promiscuity and less parenting. Men with higher testosterone are less likely to have ever married and, if they do marry, are more likely to engage in extramarital sex. The testosterone of men who marry falls as they transition from bachelor to husband, and testosterone remains low among stably married men.

At the neural level, the hormones oxytocin and vasopressin appear to be involved in the formation of pair bonds between males and females. Recent insight into the neuroendocrine basis of monogamous pair bond formation comes from the comparative study of two rodent species. The prairie vole and the meadow vole are two very closely related species that differ markedly in mating strategies. Male and female prairie voles form lifetime pair-bonds, whereas meadow voles are highly promiscuous. During copulation, oxytocin and vasopressin are released in the brain. Oxytocin facilitates affiliation and partner preference behavior in female prairie voles, and vasopressin facilitates affiliative and parenting behavior in male prairie voles. Exogenous injections of vasopressin to the male prairie vole and oxytocin to the female facilitate mate preference behavior without the occurrence of mating. Likewise, blocking the receptors for these hormones will prevent pair-bonding from occurring after copulation. In contrast, similar injections do not influence social behavior in the meadow vole.

Though human brains release oxytocin and vasopressin during sex, relatively little is known about their precise functions in humans. Nevertheless, findings from other species provide a starting point, and ongoing efforts to understand the changes in gene expression for oxytocin and vasopressin receptor density may help to clarify individual differences in human mating strategies.

SEXISM

Sexism commonly describes attitudes, statements, acts, strategies, or methods that lead to the discrimination, marginalization, or oppression of individuals or groups based on their sex. Coined by the New Women’s Movement during the 1970s, the term was rapidly employed by the newly developing fields of women’s and gender studies as a tool to analyze processes that discriminated against and marginalized women. Sexism against women pervades all areas of their lives, public and private, legal and economic, educational and social, religious and psychological, and gender relations in particular. It chiefly manifests itself in disparaging attitudes and behavior toward women and can legitimize their harassment, rape, and trafficking. Like racism, sexism has affected the lives of women worldwide and throughout history.

In philosophical thought, sexism is considered a subcategory of essentialism, a term British philosopher Karl Popper (1902–1994) introduced in 1935. In present-day women’s and gender studies, the term essentialism usually has a pejorative, or derogatory, meaning, due to the models of biological determinism associated with it. For example, essentialist positions claim that all members of a group share a permanent and inalterable list of characteristics, such as the idea that women across all historical and cultural boundaries exhibit certain “womanly” attributes like motherliness. Essentialist thought has contributed to establishing gender as a distinct category of analysis, a distinction that a number of feminist authors, most notably Judith Butler (b. 1956), started to dismiss in the 1990s. Essentialist arguments, especially in gender discourses, tend to side with conservative political thought and the upholding of the status quo, thus often contributing to sexism. They are, however, sometimes used by progressive political groups such as the gay rights movement, which claims that homosexuality is rooted in biology.

Extreme forms of sexism against females are called misogyny, or hatred of women. Misogyny, or its weaker form, gynophobia (fear of women or femininity), is usually ideologically or psychologically founded. It is expressed in sexist attitudes and practices and can be institutionalized in political or social structures. Unlike antifeminism, a term that is often used synonymously but refers to attitudes against women’s emancipation, misogyny implies an inherent inferiority of women and thus represents essentialist ideas of femininity. A second form of sexism commonly identified is sexism against men, also known as reverse sexism. Like sexism against women, it can develop extreme forms, called misandry, or hatred of men. A milder form is called androphobia (fear of men or masculinity). While the sexist view that women are superior to men is not as prevalent, it has become part of the public discourse.

The publication of Kate Millet’s Sexual Politics (1970), which challenged the myth of a “natural” difference between the sexes and the resulting hierarchical social structures that considered men superior, laid the groundwork for a comprehensive critique of sexism by feminists, mainly in the United States and Europe. Millet’s book focused on dominant theories in literary analysis and revealed the sexist nature of the literary canon, but she also analyzed psychological, sociological, and anthropological theories that cause and reinforce existing hierarchies between the sexes and define a woman as something that deviates from the (male) norm.

In the 1970s other feminist scholars and activists in the United States and Europe began to analyze and challenge sexist practices in schools and other educational institutions and identified various ways schools discriminated against girls. Among their most important grievances were sex-biased curricula and textbooks, practices of
classroom interaction favoring boys, sex-typed course and career counseling, and male domination in math and science classes as well as in educational administration. Obviously, some of these problems are easier to rectify than others—policy decrees, for example, can successfully be employed to change the contents of textbooks but may be less effective in altering sexist classroom interaction.

The study of sexist language, gestures, and behavior became another focus of feminist academics and activists who identified various strategies employed to ignore women in academic and everyday discourse to make them “invisible” or silence them by sexist jokes or male “codes.” Other studies found that sexist attitudes and practices were widespread in the workplace to marginalize women and keep them away from higher paying jobs, both white and blue collar, which are considered fields reserved for men.

SEXUAL HARASSMENT
Feminist legal scholars and lawyers started to battle sexism, specifically sexual harassment, in the economic world. Originally defined as treatment that persistently provokes, pressures, frightens, and otherwise discomforts coworkers, harassment has increasingly acquired a sexual component not restricted to demanding sexual favors but rather identifying discriminatory demands such as wearing gendered forms of dress or performing stereotypical feminine duties not included in the job description. In 1991 the media coverage of Supreme Court Justice Clarence Thomas’s confirmation to the U.S. Supreme Court, which spotlighted the claims of sexual harassment alleged by his former employee Anita Hill, was central to installing both forms, *quid pro quo* and hostile work environment harassment, into the public mind. Largely an American invention, sexual harassment continues to generate much controversy. While a narrow sexual definition of harassment has undergone some criticism in the United States, chiefly due to supposed vague standards and an infringement of the right to free speech, this definition has begun to spread to other nations around the globe.

In the United States in particular, the antidiscrimination measures of the 1970s and 1980s have largely succeeded in making sexist attitudes and practice socially unacceptable. Many experts think, however, that the rapid changes in gender roles that occurred in the family and the workplace during those decades were the main cause for the transformation of gender relations in other areas of social life. Some scholars find that at the beginning of the twenty-first century, sexism ceased to be an exclusively female problem and sexist attitudes against men are on the rise. Masculinist movements and fathers’ rights organizations, for example, have started to promote men’s rights and have addressed a number of legal issues in particular, such as paternity leave and equal access to children. Other experts contend that sexism is becoming less relevant altogether, at least in industrial societies. Undoubtedly, gender biases and sexist practices remain more intact in societies where women are limited to the private sphere.

**SEXUAL ABUSE**

**SEE** Torture.

**SEXUAL HARASSMENT**

Sexual harassment is the creation of an overtly sexualized work or school dynamic that adversely affects the experience of one or more workers or students. The “sexual” in sexual harassment relates to motive rather than content; while sexual harassment may involve sexually explicit language, images, or actions, the key is that the person being harassed is targeted because of his or her gender. Sexual harassment may be perpetrated by an individual or a group; perpetrators and victims may be of opposite genders or the same gender, men or women. In many jurisdictions, sexual harassment is illegal; workers or students who are adversely affected by harassing behavior may seek compensation through the courts.

In the United States, Title VII of the Civil Rights Act of 1964 prohibits gender-based discrimination in the context of employment and imposes civil liability on employers who engage in or tolerate such behavior. The text of Title VII makes it “an unlawful employment practice for
an employer … to discriminate against any individual with respect to his compensation, terms, conditions, or privileges of employment, because of such individual’s … sex.” Originally, lawmakers and judges understood the statute to prohibit disparate treatment of men and women with respect to the tangible and economic aspects of employment: hiring, promotion, retention, pay, and economic benefits.

Even under this limited understanding of Title VII, courts recognized that one form of sexual harassment—called “quid pro quo sexual harassment”—was prohibited. This most explicit form of sexual harassment involves a person in a position of authority making express sexual demands on a subordinate with an implied or overt threat of retaliation if the sexual demands are not met. For example, if a supervisor tells a subordinate that he can keep his job only if he is willing to engage in sexual acts with the supervisor, that is quid pro quo sexual harassment.

In 1986, the U.S. Supreme Court recognized a more subtle—and more controversial—form of actionable sexual harassment: “hostile work environment” sexual harassment. A hostile work environment may be created through unwanted sexually suggestive remarks, sexually charged jokes, or sexual touching. The key difference between a claim of quid pro quo sexual harassment and hostile work environment sexual harassment is the injury or harm experienced by the victim; in a hostile work environment claim, the alleged harm is psychological stress rather than an explicit deprivation of job benefits. Sometimes hostile work environment claims involve an allegation of “constructive discharge”: The work environment was so hostile, so unbearable, that the victim felt compelled to quit and was thus constructively discharged from employment.

Champions of equal rights hail laws prohibiting both quid pro quo and hostile work environment sexual harassment as important tools for equalizing the economic opportunities of men and women. One of the more controversial sexual harassment cases in U.S. history, Jensen et al. v. Eveleth Taconite Company, involved women hired to work in a talc mine in Eveleth, Minnesota; the case was significant because it was the first sexual harassment case successfully brought as a class action. In journalistic accounts of the litigation, many of the women noted that the mines offered wages dramatically higher than those offered by any other employers in the area. For many of the women involved in the litigation, they had to work at the mine or collect welfare benefits to feed their children.

Critics of hostile work environment claims charge that the line between a relaxed and collegial work environment and a hostile environment is not clear enough for employers to develop workable human resources policies.

The U.S. Supreme Court has attempted to address this issue by insisting that Title VII is not a “general civility code” (Oncale v. Sundowner Offshore Services, Inc., 523 U.S. 75 [1998]); “[w]hen the workplace is permeated with discriminatory intimidation, ridicule, and insult that is sufficiently severe or pervasive to alter the conditions of the victim’s employment and create an abusive working environment, Title VII is violated” (Harris v. Forklift Systems, Inc., 510 U.S. 17, 21 [1993]).

Although most sexual harassment law focuses on the work environment, sexual harassment can occur and even be legally actionable in other contexts. Most notably, as mentioned above, sexual harassment may occur in a school environment. In the United States, Title IX of the Education Amendments of 1972 prohibits gender discrimination in education. Courts have construed Title IX to prohibit sexual harassment; students who are sexually harassed by teachers, administrators, or even other students may have a cause of action against the school that tolerated the harassment.

SEXUAL ORIENTATION, DETERMINANTS OF

A person’s sexual orientation concerns whether he or she is sexually attracted to people of the same sex, the opposite sex, or both. Starting in the nineteenth century, scientists, physicians, and mental health specialists have offered numerous theories of how people develop sexual orientations. What determines a person’s sexual orientation remains a question of much scientific, psychological, and social scientific controversy. Current biological theories focus on genes, brains, and hormones.

For much of the twentieth century, scientists believed that gay men and lesbians had gender-atypical hormone levels in their bodies; for example, they thought that lesbians had more testosterone and less estrogen in their systems than did heterosexual women. Recent studies have shown that almost all lesbians and gay men have the same
Sexual Orientation, Determinants of

circulating hormone levels as their heterosexual counterparts. In response, current hormonal theories propose a link between sexual orientation and prenatal hormone levels. As prenatal hormone levels play a role in the organization of the developing brain, the idea is that different prenatal hormones levels could explain sexual orientation differences among adults. This prenatal hormonal hypothesis is premised largely on observations that early hormone exposure determines both the repertoire of mating behaviors exhibited by laboratory animals and the morphology of particular brain regions believed to modulate those behaviors.

BRAINS

Over the past few decades, confirmed sex differences in the size of several brain structures in various laboratory animals have lead to speculation regarding parallel differences in the human brain associated with sex and sexual orientation. Several of the structural sex differences identified in animals involve specific cell groups in a region of the rodent hypothalamus involved in regulating particular mating behaviors. One such anatomical sex difference in rodents develops in response to sex differences in early exposure to sex hormones and involves a part of a rodent's hypothalamus called the sexually dimorphic nucleus of the preoptic area (SDN-POA). In the laboratory, damage in the vicinity of the SDN-POA decreases mounting behavior, and electrical stimulation of the region elicits mounting behavior. These observations established the belief that the SDN-POA participates in regulating male sexual behavior. That belief lacks critical support because the destruction of the SDN-POA of male rats does not, however, disrupt mounting behavior. The function of the SDN-POA remains to be elucidated.

The belief that the SDN-POA participates in regulating sex behavior in rats led to the search for a comparable nucleus in humans. The human third interstitial nucleus of the anterior hypothalamus (INAH3) has been identified as the most promising candidate. This nucleus is much larger and contains substantially more neurons in presumed heterosexual men than in women. By extrapolation from animal work, this human sex difference is widely believed to reflect sex differences in early hormone exposure, but this hypothesis is exceedingly difficult to test in humans. The AIDS epidemic has, however, made it possible to study this nucleus in men whose medical records indicate homosexual behavior. These studies suggest that the volume of INAH3 may be smaller in homosexual men than in heterosexual men; however, that finding must be viewed tentatively for various reasons, including that all the homosexual men in these studies died from complications of AIDS.

Researchers have also sought to identify variation with sex and sexual orientation in the bundles of fibers that connect the left and right hemispheres of the brain. These studies have produced conflicting results regarding variation with both sex and sexual orientation.

GENES

Inside each person's cells are chains of DNA that act as a recipe for making that person. Determining the role a portion of genetic material plays in the development of a particular human trait is complicated, although there has been some success for specific anatomical and physiological traits. It is much more difficult to identify genetic material that influences complex psychological traits such as sexual orientations. One way to infer the extent to which a trait is genetic is to study twins. Identical twins share 100 percent of their genetic material. Fraternal twins are genetically only as closely related as non-twin biological siblings, sharing only 50 percent of their DNA. Because identical twins are genetically identical, differences between them are due to their pre- or post-natal environment, not genes. This inference does not work in the other direction. If identical twins have the same trait, it might be because they were raised in the same environment.

Sophisticated studies have assessed sexual orientation in identical twins, same-sex fraternal twins, non-twin biological siblings, and similarly-aged unrelated adopted siblings. The idea is that if sexual orientation is genetic, identical twins should have the same sexual orientation, and the rate of homosexuality among the adopted siblings should be equal to the rate in the general population. If, on the other hand, identical twins and adopted siblings are as likely to have the same sexual orientation, then genetic factors make very little contribution to sexual orientation. Subjects recruited through ads in gay publications looking for volunteers with twins of the same sex were asked to rate their own sexual orientation, the sexual orientation of their relatives, and for permission to contact their siblings. In these studies, identical twins of gay men and lesbians were substantially more likely to share their sibling's sexual orientation than were fraternal twins.

The result of such twin studies are difficult to interpret because gays and lesbians seem more likely to volunteer themselves and their twin siblings for such studies when they have gay or lesbian siblings. When the proportions of identical and fraternal twins who are concordant for homosexuality are examined in databases of twins who were not selected on the basis of sexual orientation, the estimates for heritability of homosexuality are much lower than when subjects are selected from newspaper ads recruiting on the basis of sexual orientation.

Building on the twin studies, scientists have tried to isolate the portion of the human genome that hypotheti-
cally influences sexual orientation. One such study began with the observation that some studies had found that homosexuality in men seems to follow the maternal line of the family. Some have interpreted this pattern among gay men's families, which has only sometimes been observed, as suggesting that male homosexuality, similar to color blindness, is inherited from one's mother on the X chromosome. To test the hypothesis that the X chromosomes contains genes that influence sexual orientation, families with at least two gay brothers were recruited from a sample of families in which homosexuality appeared to follow the maternal line. DNA samples were obtained from two gay brothers in each subject family. Samples were then analyzed using linkage analysis to determine how frequently the gay brothers had inherited markers from the same X chromosome of their mother. Because mothers have two X chromosomes but only pass one to their sons, one would expect two sons to have a 50 percent chance of sharing markers from the same maternal X chromosome. One research team, however, reported that when both sons were gay, 64 percent appeared to have inherited a particular portion of the same maternal chromosome (known as the Xq28 region). This finding was interpreted as suggesting that genes influencing sexual orientation in men may reside on the Xq28 region. That suggestion must be viewed cautiously because it has been criticized on the basis of multiple technical and statistical concerns, and two independent research teams have failed to replicate it.

More generally, linkage analysis is best suited for discovering the genetic basis of traits determined in a genetically simple manner rather than traits that are influenced by several genes working in concert. This technique has mistakenly indicated that a specific genetic sequence plays a role in the development of a particular trait. Such mistakes are especially likely in the case of genetically complex traits, cognitively mediated psychological/behavioral traits, or those traits strongly affected by environmental factors.

In addition to linkage analysis, some studies have looked for differences related to sexual orientation in candidate genes chosen on the basis of their involvement in the hormonal mechanisms of sexual differentiation and development. To date, these studies have not produced positive findings.

In any event, genes in themselves cannot directly cause a behavior or a psychological phenomenon. Genes direct RNA synthesis that in turn leads to the production of a protein that may influence the development of psychological dispositions and particular behaviors. There are many intervening pathways between a gene and a behavior or a behavioral disposition and even more intervening variables between a gene and a cognitively mediated behavior.

None of the most popular scientific theories of the determinants of sexual orientations are well supported. This does not mean, however, that sexual orientations are not biological in the sense that all psychological phenomena require the activity of a living brain. Rather than asking whether or not sexual orientations are biological, the more salient question is what role biology plays in the development of sexual orientations. Biology would still be a factor in sexual orientation if there are multiple pathways to the development of a particular sexual orientation. Biological factors may also play a role if they influence temperamental or personality factors that shape how a person interacts with the environment and experiences of it, which in turn affects the development of one's sexual orientation.

SEXUAL ORIENTATION, SOCIAL AND ECONOMIC CONSEQUENCES

Sexual orientation is generally considered a personal characteristic that reflects an individual's sexual behavior, attraction, or self-identity. Individuals can have a primary orientation toward others of the same sex (gay, lesbian, or
homosexual people), toward people of both sexes (bisexual people), or toward people of a different sex (heterosexual people). Social scientists have studied the influence of sexual orientation on social and economic outcomes by comparing the experiences of lesbian, gay, and bisexual (LGB) people with those of heterosexual people. Overall, research shows that sexual orientation is an important influence on health and on economic and social wellbeing.

In discussions of the social and economic effects of sexual orientation, most interest is focused on LGB people. While controversy exists over exactly how many LGB people live in the United States or other countries, most studies find that 2 to 6 percent of people report sexual behavior, attractions, or a self-identity toward people of the same sex, making people who are LGB a clear sexual minority in numerical terms. Furthermore, heterosexuality is generally the socially accepted sexual orientation, while being LGB is often considered an inferior and stigmatized status. Stigma puts LGB people at a social and economic disadvantage and implies that their lives may be affected by prejudice and discrimination.

One important characteristic of sexual orientation influences the kind of disadvantages experienced by LGB people. Sexual orientation is not a visible characteristic, unlike age, race, or sex, and therefore LGB people can sometimes keep their sexual orientation invisible or allow others to assume that they are heterosexual. Invisibility sometimes allows LGB people to escape ill-treatment, but the activities and effort required to hide sexual orientation—commonly known as being “in the closet”—may be considerable and can cause psychological and physical stress, not to mention social discomfort.

When LGB people “come out” of the closet and become more visible in their families, workplaces, and communities, they may be subjected to behavior that reflects prejudice, such as vocal disapproval, social rejection, discriminatory treatment, or even physical violence. Both actual rejection and disapproval and the fear of rejection and discrimination reduce the participation of LGB people in their families, in religious organizations, and in some community activities. The personal effects of prejudice also sometimes include increased depression and anxiety, as well as other physical and mental health conditions. Numerous studies also show that LGB young people are more likely to consider suicide. In contrast, studies show that supportive workplace policies, laws, and coworkers create environments that encourage LGB people to come out, which often improves their workplace lives and mental health.

When some businesses tried to tap into an affluent untapped market by wooing LGB consumers beginning in the 1990s, some people and policymakers wondered whether LGB people actually face economic discrimination. However, many studies by economists show that the reality of economic disadvantage trumps the myth of gay affluence. Gay men earn less than heterosexual men with the same job-related characteristics, with a pay gap of 10 to 32 percent in the United States. Lesbians earn no more than comparable heterosexual women, and in some studies they earn more than heterosexual women. However, the gender pay gap means that a lesbian couple always earns less than a heterosexual married couple and less than a gay male couple, so lesbians are also not the “dream market” that businesses are said to seek. Also, many employer benefits policies extend health care or survivor benefits to the spouses of employees, but only a minority of employers grant those same rights to LGB employees’ same-sex partners, resulting in lower total compensation for LGB employees.

Scholars do not agree on the causes of the wage patterns. Some argue that gay men’s earnings disadvantage reflects discrimination in the labor market, an argument bolstered by the fact that few states (or countries) forbid employment discrimination based on sexual orientation. Others argue that the wage variances stem from variations in family formation for LGB and heterosexual people. A gay man who partners with another man may not need to support a partner and children, reducing gay men’s incentives to gain added job skills and experience and eventually reducing gay men’s earnings relative to heterosexual men who might plan to be a sole provider for a family. However, the fact that gay men have more education than heterosexual men suggests that gay men’s commitment to investing in job-related skills is at least as strong as for heterosexual men. Likewise, lesbians know that they will not have a male partner, so they might have more skills and experience than heterosexual women, who might also be more likely to leave the labor market for short periods to raise children or do other family-related work. This compensation for differences in family structures could disguise or compensate for any less visible discrimination that lesbians might face that would otherwise reduce their earnings.

The issue of partnership highlights another realm of social and economic disadvantage for LGB people in creating families. Census 2000 counted roughly 600,000 same-sex couples in the United States, with one in three female couples and one in five male couples raising children under eighteen years old. However, in most places LGB people form these families in the absence of access to marriage or full parental rights. Several countries (beginning with the Netherlands, Belgium, Spain, and Canada) and the state of Massachusetts allow same-sex couples to marry, while some other states and European countries provide a different and usually lesser form of legal recognition for same-sex couples. Without the right to marry,
Darwin said that secondary sexual characters could evolve in one of two ways. First, they could be useful to one sex, usually males, in fighting for access to members of the other sex. Weapons like the antlers on male ungulates or horns on male beetles are advantageous because better fighters get more mates and have more offspring. The second way was more problematic. Noting that females often pay attention to traits like long tails and elaborate plumage during courtship, Darwin concluded that the traits evolved because the females preferred them. The sexual selection process, then, consisted of two components: male-male competition, which results in weapons, and female choice, which results in ornaments.

Although competition among males for females seemed reasonable to Darwin’s Victorian contemporaries, the idea that females could do anything as complex as discriminate between males with different degrees of development of a character like colorful plumage was one they could not swallow. Alfred Russel Wallace, who independently arrived at some of the same conclusions about evolution and natural selection as Darwin, was particularly vehement in his objections.

Largely because of this opposition to the idea of female choice, sexual selection as a theory lay dormant for several decades. It was not until the 1960s that evolutionary biologists began to reconsider the portrait they had painted of animal social life. Probably the most important new insight came from work by Robert Trivers, who pointed out that females and males differ in how they put resources and effort into the next generation, which he termed parental investment. Females are limited by the number of offspring they can successfully produce and rear. Because they are the sex that supplies the nutrient-rich egg and often the sex that cares for the young, they leave the most genes in the next generation by having the highest quality young they can. Which male they mate with is important because a mistake in the form of poor genes or no help with the young could mean that they lose their whole breeding effort for an entire year.

Males, on the other hand, can leave the most genes in the next generation by fertilizing as many females as possible. Because each mating requires relatively little investment, a male mating with many females sires many more young than a male mating with only one female. Hence males are expected to compete among themselves for access to females, and females are expected to be choosy and to mate with the best possible male they can.

A classic example is the elephant seal. These animals spend most of the year at sea. In late fall males arrive at isolated beaches and establish a dominance hierarchy, often by vicious fighting and throwing around of their weight, which can exceed three tons. Female elephant seals, about a third the size of males, arrive later, already

SEXUAL SELECTION THEORY
Although Charles Darwin is best known for his theory of evolution by natural selection, he was also fascinated by the differences between males and females in all species. His 1871 book, The Descent of Man and Selection in Relation to Sex, documented those differences and suggested an explanation for them. Darwin pointed out that traits such as peacock tails that occur in only one sex could be of two types: The primary sexual characters enable males to produce sperm and females to produce and nurture eggs; the evolution of these traits is easy to explain via natural selection. The secondary sexual characters, such as the long tails and bright colors of many male birds or antlers on male deer, are often detrimental to survival, either because they make males more conspicuous to predators, or because they are physiologically costly to produce.

couples have no access to important legal rights and benefits that enhance family security and economic well-being.

The social and economic differences in treatment across sexual orientation outlined here have prompted a growing social and political movement around the world to reduce stigma and prejudice and to improve the well-being of LGBT people. As a result of these efforts, more LGBT people are living open lives, more jurisdictions forbid discrimination based on sexual orientation, more employers treat LGBT and heterosexual employees equally, and more states and countries are granting rights to same-sex couples.

Sexual Selection Theory
pregnant. Males herd them when they get to shore; after having her pup, a female is sexually receptive and mates with (usually) the male who has herded her and controls her movements. Males that can sequester more females have a chance for enormous payoffs: A study of an elephant seal colony showed that, in one year, a single male fathered about 90 percent of the pups in the colony. It thus pays to compete with other males because males that do so leave more genes in succeeding generations. Females, on the other hand, have one pup regardless of how many males they mate with. This species is oriented more toward male-male competition than female choice, and the best fighter wins.

In other species female choice predominates. For example, satin bowerbirds are members of a family in which males build elaborate structures during the breeding season. The male collects objects and carefully places them around the bower, after which he waits by it for a female to approach. If she does, he begins a species-specific display that may involve song, complicated courtship dances, or other enticements. Sometimes the female is won over, stays with the male, and mates. Sometimes she watches for a while and leaves. Either way, her choice determines the outcome.

In a handful of species the usual pattern is reversed: Males provide a large contribution to females and offspring, while females benefit by mating with many different males. Katydid males, for instance, sing to attract females for mating. But once a female arrives, she stands to gain much more than a fertilization of her eggs. The males of many katydids produce a gelatinous, nutrient-rich structure called a spermatophylax, which is given to females along with a packet of sperm and which the female eats while the sperm is fertilizing her eggs. It supplies her with protein she often does not get in her usual diet, which enables her to lay more eggs. Females with larger nuptial gifts, as they are called, have more offspring.

But the gifts have an even bigger return if the female recipient is herself relatively large, because larger females lay more eggs. A male cannot give many spermatophylaxes to females in a season, as they can average up to 30 percent of his weight. Therefore, in many species of katydids, male choice rather than female choice occurs, with males seeming to gauge the size of prospective mates and rejecting them if they are too light. Male competition in katydids is much less important than male mate choice; instead, female competition may be a major force, and males choose from among available females. This further supports the notion that the crucial factor is which sex limits the reproductive capacity of the opposite sex.

SEXUALITY
Surveys of human sexuality serve several purposes. They provide reports of sexual norms to supplement information from sources such as media, church, and medicine. They expand the vocabulary for discussing sexual desire and behavior. They offer a unique and fascinating lens through which to examine social trends. Finally, findings from scientific sex surveys provide evidence for public policy initiatives, education, treatment, and funding regarding sexual health and the prevention of sexually transmitted infections.

Nearly 750 sex surveys were conducted in twentieth-century America. These range from massive nationwide investigations to small scholarly studies to questionnaires in consumer magazines such as Redbook, Cosmopolitan, and Playboy. The focus of these surveys ranges widely as well, covering subjects as diverse as marriage, divorce, fertility, contraception, masturbation, intercourse, orgasm, abstinence, gender equality, homosexuality, rape, adolescence, aging, sex education, pornography, and sexually transmitted infections. This entry highlights a few of the large American sex surveys and indicates their contributions and the story they tell about our culture.

OUR VICTORIAN FOREMOthers
The earliest American sex survey was a study of forty-five wives by Stanford physician Clelia Mosher (1863–1940), conducted between 1892 and 1912. Mosher’s findings

SEE ALSO  Human;  Hierarchy;  Natural Selection
suggest that women at the turn of the twentieth century may have been much more erotically responsive than the stereotypical corseted, repressed Victorian housewife. In fact, for Mosher’s respondents, marital unhappiness was caused less by wifely frigidity than by sexual desires their husbands were unable to gratify.

In 1929 another female physician, Katharine Bement Davis (1860–1935), surveyed 2,200 women, including unmarried women and lesbian women. Her findings reveal how little sex education was available to women at that time. Although 56 percent of her sample reported that they had had “adequate instruction” before marriage, their responses show that information was limited to anatomical facts and that these women longed for more knowledge about the relational aspects of sex and the “sex emotions.” (Davis 1929, p. 64). Again, these women were more sexually responsive than one might predict of early twentieth-century women. Nine percent of Davis’s respondents reported intercourse daily or more often, some over a span of many years. Many reported sexual fantasies, frequent masturbation, and also mutual masturbation with male and with female partners. One woman reported experiencing sleep orgasms (Davis 1929, p. 359), another said she became “drunk on erotic passages in books” (p. 291), and another reported the ability for spontaneous orgasm, that is, orgasm without physical touch: “I can induce ‘that queer feeling’ almost any time by thinking about it” (p. 191). The sexological literature did not investigate the phenomenology of spontaneous orgasm until more than sixty years later, when researchers Gina Ogden and Beverly Whipple did so (Whipple, Ogden, and Komisaruk 1992).

INVESTIGATING MARRIAGE: NARROWING THE DEFINITION OF SEX

During the 1920s, 1930s, and 1940s, sex surveys were generally conducted by male researchers and funded by universities or government agencies, practices that have continued into the first decade of the twenty-first century. The best-known surveys of this period focused on preserving the institution of marriage—at a time when social values had been disrupted by economic depression, two world wars, and increased independence for middle-class women, who were moving into workplaces traditionally occupied by men. While Davis was conducting her survey, psychiatrist Gilbert Hamilton (1877–1943) surveyed one hundred white, married, “highly cultured” New York couples. His questions were based on assumptions that narrowed the definition of sex and laid down the pattern for subsequent surveys. Some of these assumptions were:
Sex meant penis-vagina intercourse, whereas romance, kissing, and petting meant preparation for intercourse (hence the notion of foreplay).

Sexual satisfaction meant physiological orgasm with vaginal spasms that could be measured.

Sexual interest was proportional to the number of partners a respondent reported.

Hamilton’s survey did not inquire about physical aspects of sexual response beyond intercourse, or about the emotions or meanings of sex. This and subsequent surveys found men to have more interest in sex than women—more partners, more frequent intercourse, and earlier first intercourse. Women were found to be less interested and satisfied—with some 80 percent anorgasmic on intercourse.

KINSEY AND FOLLOWERS: THE QUANTIFICATION OF SEX

Alfred Kinsey (1894–1956) and his colleagues introduced quantitative methods and random sampling that set the gold standard for all future sex survey methodology. The Kinsey Reports were the first massive investigations of American sexual behavior. *Sexual Behavior in the Human Male* (5,300 men) was published in 1948. *Sexual Behavior in the Human Female* (5,940 women) was published in 1953. These Kinsey surveys addressed six “outlets” of sexual response: masturbation, petting, homosexuality, premarital intercourse, extramarital intercourse, and intercourse with animals. Perhaps Kinsey’s best-known contribution was his notion that sexual orientation is not necessarily fixed, but often fluctuates over a range of behaviors and fantasies during the lifespan. He placed heterosexuality and homosexuality on a continuum—using a zero-to-six scale. On this scale, “zero” indicates that sexual desires and behaviors involve only partners of the opposite sex, and “six” indicates that sexual desires and behaviors involve only same-sex partners. Most of us fall somewhere between, said Kinsey—hence a “Kinsey-three” indicates bisexuality.

The Kinsey questionnaires were exhaustive, with hundreds of questions, many doubling back to validate earlier ones. In addition, Kinsey trained interviewers to ask questions that were designed to be nonjudgmental and to minimize yes-or-no evasions. He assumed that all of his respondents had rich sexual experiences. For instance, to explore the still taboo subject of masturbation, Kinsey instructed his interviewers to ask: “How do you masturbate?” rather than “Do you masturbate?” This technique placed the burden of negative proof on the respondents—and as illustrated in the 2004 movie *Kinsey*, gave permission for even shy respondents to tell eloquent stories.

Far-reaching as these Kinsey questions were, they nonetheless focused on the performance aspects of sex and omitted emotions and meanings, which Kinsey stated had no place in scientific inquiry. For Kinsey, orgasm was the index of sexual health, and number of partners was the index of sexual interest.

Two large random surveys acted as follow-ups for American sexual attitudes in the generations after Kinsey. Morton Hunt’s 1974 survey of 2,026 women and men, *Sexual Behavior in the 1970s*, was sponsored by Playboy magazine and showed an increase in oral sex and intercourse outside of marriage. Edward Brecher’s (1911–1989) survey of 4,246 women and men, *Love, Sex, and Aging* (1984), sponsored by the Consumer’s Union, showed that the Kinsey generation, now age fifty and older, was still sexually active.

THE SEXUAL REVOLUTION: GAYS, LESBIANS, AND WOMEN

In 1969 the Stonewall riots in New York City ignited national consciousness about gay rights (Carter 2004). During the 1960s and into the pre-AIDS 1980s, a number of sex surveys focused on gay and lesbian behaviors. Allen Bell and Martin Weinberg (1977) surveyed 4,639 gay men and lesbian women. Their questionnaire, too, was based on performance; the findings suggested that gay men were more interested in sex—as defined by genital stimulation, physical orgasm, and number of partners—and that lesbian women were more interested in romantic emotional commitment. *The Gay Report* (1979) by Karla Jay and Allen Young surveyed another 5,000 gays and lesbians and came to a more complex conclusion: that lesbians engaged in plenty of sex, but defined it more broadly than gay men did—including love, relationship, and their partners’ pleasure, as well as genital stimulation and multiple partners. In 1983 sociologists Philip Blumstein and Pepper Schwartz corroborated this view in their survey of heterosexual and gay couples—a total of 6,066 individuals. In their report, *American Couples*, they wrote that lesbians’ reports of sex were usually not genital focused and that heterosexual men and women diverged on what they considered sexual experience to include.

The changing roles of women were a major focus of this period. Sociologist Shere Hite’s 1976 survey of 3,019 women popularized the notion of clitoral orgasm to challenge the male-centered focus on penis-vagina intercourse. Her findings were criticized by the scientific establishment because her respondents, drawn largely from the National Organization for Women (NOW), were self-selected rather than randomly selected. Nonetheless, *The Hite Report* became an international best seller as it reflected women’s political and medical advances toward sexual
freedom. In 1960 the birth control pill had provided a means of avoiding unwanted pregnancy, in 1973 the U.S. Supreme Court’s Roe v. Wade decision legalized abortion throughout the country, and various sex-positive books for women had paved the way for Hite’s material, especially Our Bodies, Ourselves (1970), Betty Dodson’s Liberating Masturbation (1974), and Lonnie Barbach’s For Yourself (1975).

Hite’s popularity ushered in a boom of further sex surveys by women in the 1980s and 1990s, especially questionnaires in large-circulation women’s magazines. The Redbook Report on Female Sexuality (1977) by social psychologists Carol Tavris and Susan Sadd had over 100,000 respondents—married women, who disclosed “the good news about sex.” Yet these women’s surveys reverted to the usual indicators for sexual satisfaction: interest in intercourse, number of partners (usually heterosexual), and orgasm as goal.

THE GENDER GAP IN SATISFACTION

The last large institutional sex survey of the twentieth century (3,432 men and women) was conducted by Edward Laumann and three colleagues: John Gagnon, Robert Michael, and Stuart Michaels. Published in 1994 as The Social Organization of Sexuality, the survey’s purpose was to research risk factors for HIV/AIDS and other sexually transmitted infections. But the findings harked back to pre-Kinsey surveys that focused on commitment and marriage while downplaying affairs, casual sex, and gay and lesbian relationships. Also like the pre-Kinsey surveys, the Laumann findings underscored the sexual shortcomings of women. The highly publicized statistic that emerged from the Laumann findings is that 43 percent of the women respondents reported sexual dissatisfaction or dysfunction, as distinct from 31 percent of the men. This gender discrepancy in satisfaction was reaffirmed in Laumann’s 2006 survey of 27,500 people in twenty-nine countries and reflected what has become a thematic limitation of sex survey research: focus on intercourse and omission of meaningful issues such as attraction, love, intimacy, and commitment.

In the late 1990s, two large independent surveys were conducted by sex therapists. Their survey questions, largely drawn from their clinical practices, focused on feelings and meanings. Carol Rinkleib Ellison’s 2000 study of 2,632 women, Women’s Sexualities, conducted with Bernie Zilbergeld, underscored the developmental and intergenerational aspects of sex and love. Gina Ogden’s study, “Integrating Sexuality and Spirituality” (ISIS) (2002), showed that for 3,810 American women and men, sexual experience involved emotional, intellectual, and spiritual dimensions as well as physical. Her multidimensional ISIS model is in The Heart and Soul of Sex: Making the ISIS Connection (2006).

Into the first decade of the twenty-first century, however, institutional sex surveys continued to explore intercourse as the primary index of sexual behavior—as evidenced by the fourth cycle of the Guttmacher Institute’s National Survey of Family Growth from 1982 to 2002 (38,000 men and women), which reported that nine in ten Americans engaged in premarital intercourse. But this study did not explore the emotional or cultural dynamics that might help us understand the motivations for premarital sex, or why it is important for us to know about this behavior.

CONCLUSIONS

Sex surveys influence the national conversation about sex, but their definitive value is limited. First, these surveys skew the overall understanding of human sexual experience by omitting significant portions of the population, such as the immigrant, uneducated, and poor, who are also most at risk of sexual violence and disease, and also top echelons of the upper class, who control many of our ideas and institutions. Another limitation of sex surveys is their attempt to reduce sexual experience to numbers, which tends to reinforce stereotypes and assumptions rather than provide the nuanced information needed for assessing norms, medical interventions, and public policy initiatives. Another limitation is researcher bias. Institutional sex surveys, such as the Kinsey and Laumann studies, profess scientific objectivity. But true objectivity is impossible; all sex surveys are effectively prejudged by the questions they ask and by how the results are interpreted.

For sex surveys to expand their usefulness and influence, researchers at the institutional level need to acknowledge the intrinsic complexity of sexual experience and broaden their focus to include feelings and meanings as well as intercourse-related frequencies. In addition, they need to reach populations previously undersurveyed. Perhaps some may be reached via the Internet if the constraints of electronic reporting do not further oversimplify questions, answers, and analysis of results.

Shadow Prices

**Gina Ogden**

SHADOW PRICES

A shadow price of a resource is its value to the decision maker. Shadow prices frequently equal market prices, but there are many instances in which they differ from each other. Methods for measuring shadow prices are closely related in the constrained optimization literature of mathematical programming, and in the econometrics literature. Within the constrained theoretical optimization framework, the shadow price (often called a “dual value”) is the change in the objective function of the optimal solution, which is the result of a small change in the value of a constraint. Each constraint has an associated shadow price, which is represented by a Lagrange multiplier. This can be illustrated by considering the Lagrange multiplier associated with revenue maximization based on the sale of a commodity at price \( p \), where the firm faces the constraint that the amount available to sell cannot exceed \( X \). The optimal solution is for the firm to sell \( X \) units of \( x \), and the shadow price of \( x \) is \( p \). If one considers this same problem, but subject to a production function constraint, namely \( x = f(L) \), where \( L \) is the quantity of labor employed, the intuitive result is that the shadow price of a unit of output equals its marginal cost.

If the individual is assumed to maximize utility, then the interpretation of a shadow price becomes less intuitively obvious. Let us assume that the individual wishes to maximize the utility derived from leisure and consumption of good \( x \), subject to two constraints: (1) money stock plus earned income must equal or exceed his expenses, and (2) leisure plus work hours cannot exceed total available hours. In this case, each constraint will be binding (since neither money nor time will be wasted), and each shadow price has an interesting interpretation. The shadow price of time equals the marginal utility of leisure. The shadow price of money (expressed in “utils” per dollar) equals the marginal utility of consumption divided by the price of the good \( x \). This outcome shows that all scarce resources have a positive price, even if it is only expressed in terms of utility. That is, even if a scarce good or input is not sold directly in a market, it still has a shadow, or implicit, price. In a decentralized market, the ratio of market prices equals the ratio of shadow prices, and shadow prices are expressed in terms of utility, while actual prices are expressed in terms of dollars. When the Lagrangian takes the value of zero, its associated constraint is non-binding. With more than one constraint, additional Lagrangian multipliers are used, each with a shadow price interpretation for that resource. In economics, it is assumed that both goods and time are scarce, so that zero shadow prices do not occur.

In many cases, the shadow price differs from the actual price for a good or an input. In the industrial organization literature, this could be due to rate-of-return regulation as illustrated by Scott Atkinson and Robert Halvorsen (1984). Further, monopoly power, monopsony power, labor union regulations, distortionary taxes, sticky prices, and export/import regulations are just some of the many constraints that can cause divergences between actual and shadow prices. In the case of rate-of-return regulation for electric utilities, the shadow price of capital...
exceeds the actual price of capital, causing the utility to over-invest in capital. (Färe and Primont [1995] and Mas-Colle et al. [1995] provide many more examples of constrained cost minimization, utility maximization, profit maximization, and revenue maximization in a mathematical programming framework. In particular, Färe and Primont stress the dual relationship between various constrained optimization models.)

Econometricians have focused on estimating shadow prices (sometimes called virtual prices) for inputs and outputs that are not marketed, so that actual prices are not observed, and for inputs and outputs where shadow prices differ from actual observed prices. Robert Halvorsen and Tim Smith (1991) employ a restricted cost function to estimate the time path of the shadow price of an unextracted resource, whose actual price is not observable because of the prevalence of vertical integration in the industry. The basic technique involves taking partial derivatives of the restricted cost function with respect to the quasi-fixed input, and then employing Hotelling’s lemma.

Hedonic prices have also been estimated as shadow prices of attributes whose market prices are not available due to bundling. Hedonic regressions have a reduced form: The equilibrium price of a commodity is regressed on its attributes, which are typically not available in an unbundled form, and therefore are not separately priced. Examples are automobile price as a function of automobile attributes and housing price as a function of housing attributes. (For examples of these regressions see Atkinson and Halvorsen [1990] and Atkinson and Crocker [1987].) Hedonic prices have also been calculated to determine the value of human life, as shown by W. KipViscusi (2004).

Atkinson and Jeffrey Dorfman estimate the shadow price for tradable sulfur dioxide emission permits by calculating partial derivatives of the distance function with respect to sulfur dioxide emissions. Following Rolf Färe and Daniel Primont (1995), one divides the partial derivative of the distance function with respect to a good by its derivative with respect to sulfur dioxide, and then equates this to the ratio of the market price of this good to the unknown shadow price of sulfur dioxide. One then solves for the latter. The estimated shadow price can then be usefully compared to the market price for traded permits, as this market is quite thin.

A large additional literature has developed that maintains the hypothesis that shadow prices to the firm may differ from actual or market prices in instances where actual prices are observed. Shadow cost, shadow distance, and shadow profit systems have been developed and estimated. With shadow-cost systems, if ratios of estimated shadow prices differ from ratios of actual prices, then the firm is allocatively inefficient. Atkinson and Halvorsen (1984) and Atkinson and Christopher Cornwell (1994) assume shadow-cost minimization and estimate shadow-cost functions to compute the allocative efficiency of electric utilities and airlines, respectively. Panel data facilitates the estimation process, as shown by Atkinson and Cornwell. Atkinson and Primont (2002) extend this analysis to an estimation of a shadow-distance system, which employs the first-order conditions for cost minimization. A shadow-distance system estimates the dual to a shadow cost system by computing shadow quantities rather than shadow prices. After assuming shadow-profit maximization by firms, a shadow-profit system was devised by Atkinson and Halvorsen (1980) and Atkinson and Cornwell (1998). This system is used to estimate the shadow prices of inputs and outputs, where the latter are measures of monopoly power. Shadow prices for inputs and outputs have also been estimated to compute the extent of monopoly and monopsony power by Atkinson and Joe Kerkvliet (1989).

Attempts have been made to translate shadow-price estimates into the potential savings from eliminating allocative inefficiency. (See, in particular, Kumbhakar [1997].) However, Atkinson and Dorfman (2006) show that any such decomposition is not unique, unless at least one input’s shadow price can be related to its actual price via a factor of proportionality.

SHAMANS

Shamans represent humanity’s most ancient forms of healing, spirituality, and community ritual. In Shamanism: Archaic Techniques of Ecstasy (1964), Mircea Eliade characterized the shaman as someone who enters ecstasy to interact with spirits on behalf of the community. Although some have challenged his suggestion of the universality of shamanism, the cross-cultural research of Michael Winkelman has established the universal validity of the concept of the shaman, as well as the characteristics of Shamans, particularly their differences with respect to other types of magico-religious practitioners. In Shamanism: The Neural Ecology of Consciousness and Healing (2000), Winkelman illustrates how the cross-cultural similarities in shamans relate to humans’ evolved psychology. Shamanism was an important evolution of human culture and consciousness and created practices to expand ancient primate activities for ritual healing and group integration.

THE NATURE AND UNIVERSALITY OF THE SHAMAN

While shamans and priests are both religious practitioners, they differ in many basic ways. Shamans enter into a direct relationship with the spiritual world, for example, while priests mediate with respect to deities. Winkelman’s research, particularly in Shamans, Priests, and Witches: A Cross-Cultural Study of Magico-Religious Practitioners (1992), provides empirical evidence for these differences: Shamans of hunter-gatherer societies reflect biological adaptations to an evolved psychology involving altered states of consciousness (ASC), while priests reflect adaptations to the social leadership needs of agricultural groups.

Unlike priests who generally acquire their positions by virtue of social position in class or kinship ranks, the shaman is thought to be chosen by the spirits. Shamans acquire their special status through experiences of the spirit world. While most people in shamanic cultures may deliberately seek contact with the spirit world in a vision quest, only a few will have the benefit of being chosen by the spirits for special experiences and powers. Spirit-world experiences occur spontaneously in illness, hallucinations, dreams, and visions, and they are further induced through vision quests involving prolonged fasts; the ingestion of emetics, tobacco, and hallucinogen drugs; and other arduous techniques that provoke profound alterations of consciousness, which are interpreted as entry into the spirit world. Ritual inductions of spirit-world experiences generally employ drums, rattles, and other percussion, as well as singing and chanting.

The universals of human culture associated with shamanism involve the use of techniques for altering consciousness to produce an experience of interacting with the spirit world. These experiences are key to providing healing and information for the community. The altered states of consciousness associated with shamanism are a human universal derived from human biology, reflecting extraordinary aspects of normal systemic reactions of the brain and nervous system in maintaining homeostasis, or internal balance (Laughlin, McManus, and d’Aquili 1992; Winkelman 2000). The psychiatrist Arnold Mandell has characterized this neurobiological transcendence in terms of activation of the serotonergic linkages between the limbic (emotional) brain and the R-Complex (behavioral) brain (1980). This activation produces strong slow-wave (theta, 3-6 cycles per second) brain discharges that induce synchronized brain waves across the levels of the brain and between the frontal hemispheres.

The particular form of altered consciousness associated with shamanism is called a soul journey, soul flight, or some other similar term referring to the departure of some aspect of the self, particularly one’s soul or spirit, from the body in order to journey to the spirit world. This shamanic soul journey is distinct from the possession experiences associated with the altered states of consciousness of more complex societies. Possession involves experiences in which a person’s sense of personal consciousness and volition is replaced by the controlling influences of a spirit entity who possesses the person’s body and controls it (Bourguignon 1976). This divine control of one’s person is not typically associated with shamanic practice. The shaman remains aware of self during the soul journey, while possessed people typically report a lack of awareness of the experience following possession. Winkelman has
integrated cross-cultural and interdisciplinary explanations that suggest important influences on the nature and form of altered states of consciousness from a variety of dietary, social, political, and ritual practices. The shaman’s awareness during the soul journey reflects the active engagement in altered states through early ritual practices, while the possessed person’s sense of external dominance by the possessing entity reflects influences external to the self, such as endocrine imbalances from nutritional deficiencies and dissociate experiences induced by oppressive social conditions.

ASPECTS OF SHAMANIC PRACTICE
Shamans have additional universal characteristics that differentiate them from the priests and possessed mediums of more complex societies. Cross-culturally, shamans are characterized as charismatic leaders whose community rituals generally involve healing and divination. Other characteristics of shamans are:

• They undergo an altered state of consciousness (ASC), characterized as a “soul journey.”
• They perform rituals involving chanting, music, drumming, and dancing.
• They have had initiatory death-and-rebirth experiences and guardian spirit encounters.
• They have close relationships with animals in control of spirits and development of personal powers.
• They use therapeutic processes to recover lost souls, defined as the separation of some vital aspect of personal essence due to attacks by spirits and sorcerers.

Shamans typically engage the entire local community in all-night ceremonies. During hours of dancing, drumming, and chanting, the shaman may dramatically recount mythological histories and enact struggles in the spirit world. Shamans also have the capacity to engage in sorcery and malevolent magic to harm others.

VISIONARY TECHNIQUES EMPLOYED FOR SUPERNATURAL ENGAGEMENT
Shamans use rituals to induce the altered state of consciousness (ASC) typified in a soul journey, where a spiritual aspect departs the body and travels to the spirit world. The ASC is typically produced through drumming and dancing to the point of collapse (or deliberate repose), and it may be potentiated by dietary and sexual restrictions and medicinal plants. The overall physiological dynamics of ASC induction involve excitation until exhaustion, which induces the relaxation response, a natural recuperation process. The shaman’s ASC includes: a death-and-rebirth experience, producing a self-transformation; a flight to the lower, middle, and upper levels of the spirit world, reflecting transformations of consciousness; and personal transformation into an animal, enabling the shaman to travel and use special powers.

The shamanic ASC stimulates the reptilian and paleomammalian levels of the brain, and the associated preverbal processes. The ASC synchronizes diverse brain regions with theta brain wave discharges, which are produced by serotonergic linkages that propel these discharges from the brain stem and limbic areas into the frontal cortex. This produces an integration of lower brain processes into consciousness; an interhemispheric synchronization of the frontal cortex; and a synthesis of emotion, thought, and behavior. ASCs induce information integration, social bonding, stress reduction, and healing through enhancement of visual representation faculties. Humans have a visual symbolic system utilized in the dream mode of consciousness and illustrated in the typically visual (as opposed to verbal) material manifested in dreaming. This visual presentational symbolism (as opposed to the verbal representational system) provides a medium for manifestation of information from the preverbal levels of the unconscious. Winkelman (2000, 2002) discusses how shamanic rituals elicited and integrated this symbolic capacity to produce a new level of mental evolution underlying the development of the modern cultural capacity during the Middle/Upper Paleolithic transition approximately 40,000 years ago.

Shamanism focuses on internal mental images, evoking them through ASC and ritual practices for integrating dream processes, particularly overnight ritual activities. Shamanic visions engage psychobiological communication processes that integrate unconscious psychophysiological information with affective and cognitive levels. Shamanic images provide analysis, synthesis, and planning through integrating the informational and personal processes associated with dreaming, a visual symbolic system of self-representations involving the paleomammalian brain. Shamanic traditions recognize this use of the dream capacity in terms such as dream time. This process engages ASC induction activities that produce theta waves and induce awareness of this emotionally salient material. This integration of normally unconscious content into conscious processes produces a sense of interconnectedness and transpersonal healing experiences.

SHAMANISM AND HEALING: PSYCHOINTEGRATION
Shamans are the preeminent healers of premodern societies. Their roles as healers include medical and psychi-
Shame

Shamanic traditions produce integrative responses that synchronize divergent aspects of human cognition and identity through several mechanisms, including: (1) using ASC, ritual, and symbols to activate synchronizing brain processes; (2) the stimulation of processes of lower-brain structures and subconscious aspects of personality and self; and (3) incorporating people into community rituals that strengthen social support and identity. These therapeutic processes still have relevance in the modern world, as evidenced by the modern resuscitation of the ancient shamanic practices.

BIBLIOGRAPHY

Michael Winkelman
Beyond these considerations, there is another, broader one that is implied in Goffman’s ideas, particularly the idea of impression management. Most of his work implies that every actor is extraordinarily sensitive to the exact amount of deference being received by others. Even a slight difference between what is expected and what is received, whether too little or too much, can cause embarrassment.

Thomas J. Scheff (2006) followed Goffman’s lead by proposing that embarrassment and shame are primarily social emotions, because they usually arise from a threat to the bond, no matter how slight. The degree of social connectedness, of accurately taking the viewpoint of the other, is the key component of social bonds. A discrepancy in the amount of deference conveys judgment, and so is experienced as a threat to the bond. Since even a slight discrepancy in deference is sensed, embarrassment or the anticipation of embarrassment would be a virtually continuous presence in interaction.

In most of his writing, Goffman’s every-person was constantly aware of her own standing in the eyes of others, implying almost continuous states of self-conscious emotion—embarrassment, shame, humiliation, and in rare instances pride—or anticipation of these states. Their sensitivity to the eyes of others makes Goffman’s actors seem three-dimensional, since they embody not only thought and behavior, but also feeling.

Helen Lynd (1896–1982) was one of the first to focus on shame as a key to personal identity (1958). Silvan Tomkins (1911–1991) devoted an entire book (1963) to describing the concept of shame and its psychological and social functions. Helen Lewis (1913–1987) has shown the key role of unacknowledged shame in failed psychotherapy sessions (1971), and John Braithwaite’s work (1989) on the role of reintegrative shame in restorative justice has attracted a considerable following.

Shame and embarrassment are crucial because they have both psychological and social functions. For brevity, this entry will discuss only the three most important functions. First, for individuals, shame appears to be an automatic signal of moral trespass; the conscience has an instinctive shame component (Scheff and Retzinger 1991). This type of shame can be suppressed, but only at great cost. For most people, shame provides unmistakable signals of where they stand in their moral universe at any particular moment.

Second, normal shame signals the state of the social bond. Embarrassment and other shame signals warn us when the self or other is feeling too close (exposed, violated) or too far (invisible, rejected). If these signals are suppressed or ignored, it may be almost impossible to know where one stands with another person. Interaction takes on a stiff and formal character, with individuals flustered or distracted, which interferes with understanding and trust. Engagement and isolation produce, and are produced by, the denial of shame. Recognition of shame and embarrassment signals in others is a way of becoming aware of their humanity. Seeing that the other is embarrassed or ashamed is an elemental path toward understanding that they are persons much like ourselves.

It now seems likely that shame is a genetically inherited emotion that is a human universal. Since shame identifies threats to the social bond and to the integrity of the self, it makes sense that sensitivity to shame signals would be adaptive, and that this kind of sensitivity would have survival value for the individual and the group.

Third, shame seems to be the primary regulator of all emotions, including shame itself (shame about shame). This kind of regulation poses no problem with normal shame, because it is easily acknowledged and resolved. As indicated above, it is merely a signal of the state of the bond. But unacknowledged shame can interfere with the resolution of all the emotions, including anger, fear, grief, and shame itself. The basic reason that people hide their emotions is that they have learned to be ashamed of them. The exception is angry displays: Most people, especially men, have learned to flaunt anger and aggression as a way of masking vulnerable emotions (such as fear, shame, and grief) because they have been taught that these emotions are signs of weakness.

Since shame is a self-conscious emotion, persons and groups may fall into traps of self-consciousness that interfere with normal biological, psychological, and social paths that allow the resolution of painful emotions. For example, in the absence of unacknowledged shame, persons and groups with conflicting interests are able to find the most-beneficial or least-destructive compromise. Unacknowledged shame paralyzes both the ability and desire to reach a compromise. For this reason, unacknowledged shame and alienation may be keys to understanding interminable impasses and quarrels (Scheff and Retzinger 1991; Retzinger 1991; Scheff 1994).

For these reasons, pride and shame play an equal part with solidarity and alienation in determining the degree of social integration in a society, its capacity for cooperation and survival under stress, and its potential for fragmentation or violent disruption. Because we live in a highly individualized society, these matters have only recently come to our collective attention. Denial of shame goes hand in hand with denial of interdependence. An accurate and effective social science requires that shame and interdependence be brought to the light of day.

Sharecropping

A sharecropping arrangement is an agrarian contract between a landlord and a tenant in which the tenant pays a fraction of the crop to the landlord in exchange for the right to exploit the landlord’s plot of land. In addition to the crop rent, there may or may not be a fixed component to the contract in the form of a side payment either from the landlord to the tenant (a wage) or from the tenant to the landlord (a fixed rent). As a result, sharecropping (or share tenancy) is an alternative to (1) a wage contract, in which the landlord pays the tenant a wage but gets to keep all of the crop; and (2) a fixed rent contract, in which the tenant pays the landlord a fixed rent (either in cash or in kind) but gets to keep all of the crop. Sharecropping should therefore not be confused with a crop fixed rent contract, in which the tenant exploits the land in exchange for a fixed amount of crop per unit of land paid as rent (e.g., 1 ton of grain per hectare).

Terence J. Byres in his introduction to a collection of essays and case studies on sharecropping (1983) provides a historical perspective on share tenancy and recounts how the institution is mentioned in historical documents from ancient Greece (594–593 BCE); ancient China (722–481 BCE); ancient India (fourth century BCE); the Roman Empire (61–112 CE); western Europe, especially France, where the institution is referred to as métayage (ninth century CE); southern Europe, especially Italy, where the institution is referred to as mezzadria (ninth century CE); Russia, where the institution is referred to as polovnik, under the Mongol Empire (thirteenth and fourteenth centuries); and China and India during the twentieth century.

Sharecropping has long been reviled by social scientists—most notably by Marx-inspired economists such as Amit Bhaduri (1973) and Robert Pearce (1983), who perceived it as a mechanism by which capital (i.e., landed individuals or households) exploits labor (i.e., landless individuals or households)—but also by most economists up to Joseph E. Stiglitz (1974), as related by Alexander F. Robertson (1980). Although the Marxist critique of share tenancy may have been true during some historical periods and in some regions of the world (e.g., in the postbellum southern United States; see Reid 1973), it does not explain the persistence of sharecropping contracts that both parties enter into voluntarily, in places as diverse as the United States (Young and Burke 2001), Brazil (Stolcke and Hall 1983), Ethiopia (Pender and Fafchamps 2006), Madagascar (Bellemare 2006), India (Pandey 2004), Pakistan (Jacoby and Mansuri 2006), and so on.

THEORIES OF SHARECROPPING: THE QUASI MONOPOLY OF ECONOMICS

The study of sharecropping by social scientists has been almost the exclusive preserve of economists, and it dates back to Adam Smith’s An Inquiry into the Nature and Causes of the Wealth of Nations (1776, 1976), which viewed métayage (Smith used the French term for sharecropping, since share tenancy was still unheard of in England) as an inefficient contract between slavery and the English (i.e., fixed rent) system. Alfred Marshall, in the eighth and last edition of his Principles of Economics (1920), was the first social scientist to apply a rigorous analytical framework to the study of sharecropping, allowing him to identify the moral hazard problem associated with share tenancy. Assuming that supervision of the tenant by the landlord is prohibitively costly, the tenant will provide labor only up to the point where the value of his marginal product of labor equals the opportunity cost from entering the contract (i.e., the wage the tenant would derive from alternative employment). But then, because the tenant receives only a fraction of the value of the marginal product of labor, and given that the marginal product of labor is assumed to be decreasing, the tenant

Thomas J. Scheff
will underprovide labor with respect to a fixed rent contract. In the years following the publication of the last edition of *Principles of Economics*, the moral hazard problem associated with sharecropping—that is, the underprovision of labor by the tenant due to the fact that the landlord cannot supervise labor—has thus come to be known as “Marshallian inefficiency.”

It was not until much later, in the 1960s, that Steven N. S. Cheung, then a graduate student at the University of Chicago, sought to reestablish the efficiency of share tenancy, although an effort had been made in that direction by D. Gale Johnson, who argued that tenants have every incentive to produce efficiently given the threat of eviction by the landlord in a repeated interaction setting (Johnson 1950). By assuming that the landlord can costlessly enforce the tenant’s level of effort, Cheung showed that sharecropping can be as efficient as a fixed rent contract in a static framework (1968).

Two schools of thought were thus born. On the one hand, the Marshallian view argued that sharecropping was inefficient because it assumed that enforcing the landlord’s preferred level of effort was prohibitively costly. On the other hand, the Cheungian (or “transactions costs”) view argued that sharecropping was efficient because it assumed that the landlord could costlessly enforce her preferred level of effort.

Taking a deliberately Marshallian view, Stiglitz was the first to fully formalize the institution of sharecropping using the tools of microeconomic theory (1974). In a paper that presents and solves one of the first complete principal-agent models in economics, Stiglitz asked why sharecropping in developing countries was perceived as an inefficient (and often irrational) arrangement when the same type of contract did not raise any questions when observed under the form of commission sales in industrialized countries. Stiglitz showed that when the absentee landlord is risk-neutral and the tenant is risk-averse, sharecropping provides a useful trade-off between incentives and risk-sharing. In this case, a wage contract provides the weakest incentives to the tenant, who is also fully insured against production risk, whereas a fixed rent contract provides the strongest incentives to the tenant, who is also exposed to all the production risk. By trading off the tenant’s comparative advantage in labor supervision with the landlord’s comparative advantage in risk-bearing, a sharecropping contract remains the optimal choice among the set of inefficient contracts, i.e., it is second-best, following the terminology of contract theory. Stiglitz’s work, which contributed to the birth of the so-called information revolution in economics along with that of George Akerlof (1970) and A. Michael Spence (1973), also reestablished the rationality of sharecropping.

The theory of share tenancy put forth by Stiglitz provided the canonical model of sharecropping, but it has been refined in many ways. David M. G. Newbery incorporated a second type of uncertainty, namely uncertainty over the tenant’s wage from alternative employment, in the framework (1977). Mukesh Eswaran and Ashok Kotwal in 1985 considered the contracting problem under two-sided moral hazard—that is, moral hazard in the provision of managerial ability by the landlord and moral hazard in the provision of labor by the tenant—and showed that when each party is highly inefficient in providing the other party’s inputs (i.e., when the tenant is highly inefficient at providing managerial ability and when the landlord is highly inefficient at providing labor supervision), sharecropping emerges as the optimal contract. Clive Bell and Pinhas Zusman, instead of adopting the principal-agent framework, used the tools of cooperative game theory to study sharecropping (1976). William Hallagan abstracted from moral hazard considerations and instead chose to introduce adverse selection into the model to explain selection by the tenants into different contracts (1978). Douglas Allen and Dean Lueck took into account the fact that, in certain parts of the world, the landlord and the tenant share the cost of inputs, and that when the crop share is set equal to the cost share, sharecropping is again an efficient arrangement (1992, 1993). Maitreesh Ghiyata and Priyanka Pandey showed that in the presence of limited liability, if the tenant can choose between agricultural techniques that differ in their levels of expected yield and variance, the landlord may choose a sharecropping contract in order to curb the tenant’s risk-taking behavior (2000). Marc F. Bellemare developed theoretical explanations to account for the emergence of reverse share tenancy (i.e., sharecropping between a poor, risk-averse landlord and a richer, risk-neutral tenant), a contract that remains a theoretical impossibility under the canonical Stiglitzian theory of share tenancy (2006). This list of works is nonexhaustive, given that sharecropping is one of the most studied problems in economics and in the social sciences.

**EMPIRICAL EVIDENCE ON SHARECROPPING**

Empirically, social scientists have sought to answer two major questions regarding sharecropping: (1) Do incentives matter in land tenancy agreements—that is, are tenants less productive under share tenancy than under fixed rent, or is there Marshallian inefficiency?; and (2) Do the contract shapes observed in the data correspond to theoretical predictions? As in much of the applied literature on contracts (Prendergast 1999), the second question has received much less attention, mostly because of lack of data. Most empirical researchers asking the first question...
have found at least partial support for the hypothesis of Marshallian inefficiency (Bell 1977 and Shaban 1987 in India; Laffont and Matoussi 1995 and Ai, Arcand, and Éthier 1996 in Tunisia; Jacoby and Mansuri 2006 in Pakistan). As regards the second question, Daniel Ackerberg and Maristella Botticini found that risk-sharing concerns indeed do drive contract choice once the possibility that landlords and tenants match endogenously is taken into account in a data set of land tenancy contracts in early Renaissance Tuscany (2002); Pierre Dubois found that fertility considerations make landlords more likely to choose a sharecropping contract in an effort to curb tenants’ incentives to overuse the land and deplete soil fertility in a dataset of land tenancy contracts in a rural area of the Philippines (2002); and Bellemare found that asset risk (i.e., the possibility of losing their claim to the land) makes landlords more likely to choose sharecropping over fixed rent in a dataset of land tenancy contracts in Madagascar (2006).

Marc F. Bellemare
SHARON, ARIEL
1928–

Born on February 27, 1928, in the British Mandate of Palestine, Israeli leader Ariel Sharon's long and controversial military and political career embodies the tension between pragmatism and idealism inherent in modern nationalist movements. Oscillating between extremist Jewish ethno-nationalism and pragmatic secular Zionism, Sharon’s leadership has triggered strong and contradictory responses. It provokes hate and revulsion among the many who see him as a dogmatic and reckless bully and a war criminal. Others view Sharon with great appreciation as a brilliant strategist and pragmatic statesman who took courageous steps toward making peace with Egypt and ending the Israeli occupation in Gaza.

Sharon joined the Israeli Haganah, an underground paramilitary organization, at age fourteen. In the 1948 Arab-Israeli War he served as a platoon commander and was severely wounded in the Battle of Latrun against the Jordanian Legion. In 1953 Sharon commanded a special commando unit ("101"), which carried out retaliatory military raids against Palestinian infiltrators from refugee camps who harassed the new border settlements, trying to reapappropriate property or kill Israelis. Because of the political impact of Unit 101’s controversial operations, which targeted both civilians and Arab soldiers, Sharon obtained direct access to Prime Minister David Ben-Gurion (1886–1973) and to Army Chief of Staff Moshe Dayan (1915–1981).

Throughout his career, Sharon exploited his privileged position to undertake military operations, often despite the objections of his direct superiors. In the 1956 Suez War, Sharon led a controversial operation to conquer the Mitla Pass against orders. In the 1967 Six-Day War, Sharon distinguished himself as a strategist commanding the most powerful armored division on the Sinai front.

Sharon resigned from the army in June 1972 and was instrumental in creating the right-wing Likud Party. In October 1973 he was recalled to service following the Yom Kippur War. Commanding a reserve armored division, Sharon located a breach between the Egyptian forces, which he then used to capture a bridgehead and lead a crossing of the Suez Canal. Sharon again violated his orders by exploiting this success to cut off and encircle the Egyptian Third Army. Because of this move, which was regarded as the turning point of the war, Sharon is considered by many in Israel as a war hero who saved Israel from defeat.

As minister of defense, Sharon was the architect of the 1982 Lebanon War, bringing about the destruction of the Palestine Liberation Organization (PLO) infrastructure in Lebanon. What started as a limited operation developed under Sharon's command into a full-scale war with controversial military operations and far-reaching political goals, many of which were never approved by the Israeli cabinet. Sharon was forced to resign as defense minister after a government commission found him indirectly responsible for the Sabra and Shatila massacres, in which hundreds of Palestinian civilians in refugee camps were killed by Lebanese Christian-Maronite militias.

In 2000, shortly after the breakdown of the Camp David peace negotiations, Sharon visited the Al-Aqsa Mosque (Temple Mount) in Jerusalem. His visit was followed by a bloody Palestinian uprising (the Al-Aqsa Intifada), marking the end to the Oslo peace process and the fall of Ehud Barak's left-wing government.

In February 2001 Sharon was elected prime minister of Israel. With Palestinian violence escalating, Sharon ordered in 2002 the reoccupation of West Bank towns and the building of a controversial security fence between Israel and the occupied territories. Sharon later accepted, however, the internationally supported “road map” to peace in 2003, and in 2005 he withdrew the Israeli Army and settlers from the Gaza Strip, citing security issues. This move was opposed by many in Likud and forced Sharon into a coalition with the Labor Party. He eventually formed a new centrist party, Kadima, and declared a new election. In January 2006, just two months before the election, Sharon suffered a stroke that left him hospitalized in a coma. Kadima was temporarily leaderless until Ehud Olmert took over the party and won narrowly in the ensuing elections.

BIBLIOGRAPHY
SHARP, GRANVILLE
1735–1813
Born in Durham, England, on November 21 (November 10, old style), 1735, Granville Sharp is best known as being the prime mover in the abolition of slavery in England; one might even say that he was the force behind the British abolitionist William Wilberforce. He also launched a Bible society, saved a Christian denomination from annihilation, and even founded a nation. Such activities were matched only by his literary efforts. Although he had little formal education, his writings covered seemingly disparate topics—from Greek and Hebrew to theology, music, agriculture, and social causes, especially the cause of freedom for the black slave. An Englishman who never set foot outside his homeland, Sharp influenced the causes of liberty in three American wars (the Revolutionary War, the War of 1812, and the Civil War) by his theological-political writings.

As an indefatigable abolitionist, Sharp initiated a legal case in 1772. A slave from Virginia, James Somerset, had come to England with his master. Sharp successfully argued that either none of the laws of Virginia applied in England or all of them did. The verdict was pronounced on June 22, 1772: “As soon as any slave sets his foot on English ground, he becomes free.”

On May 22, 1787, he was elected the chairman of the newly formed Society for the Abolition of the Slave Trade because he was, in the words of his biographer, the “father of the cause in England.” Although Wilberforce was the spokesman for the society before Parliament, Sharp was especially active in getting public opinion on its side. After a twenty-year battle, in March 1807 Parliament banned the slave trade. However, the abolition of slavery from the British Empire—Sharp’s ultimate goal—would not occur until 1833, twenty years after his death, on July 6, 1813, in London.

After the American Revolution, many former slaves who had fought on the side of the British in exchange for their freedom were now homeless in the streets of London. Several of them wanted to return to their native continent, and they sought Sharp for advice. He was able to procure ships and funds from the British government, as well as a large piece of land in West Africa. The new colony, Sierra Leone, was founded in April 1787. Granville Town was the name they gave their first settlement in honor of Sharp, though the name was later changed to Freetown. In 1961 Sierra Leone became an independent state.

Sharp made three major contributions to the Christian faith, to which he was deeply committed. First, he rescued the Episcopalian denomination in America. The clergy were required to swear allegiance to the crown, an ethical impossibility after the Revolutionary War. Even as early as 1777, Sharp worked toward an independentEpiscopacy in America. Ten years later, principally because of Sharp’s influence, American clergy could be ordained without taking such an oath of allegiance. Second, in 1804 he became the first chairman of the British and Foreign Bible Society, the first Bible society in the world. Third, Sharp’s many writings (nearly seventy books and pamphlets) focused especially on integrating social causes with Christian beliefs, as well as on the original languages of the Bible (Greek and Hebrew). He is especially known for the “Granville Sharp rule,” a principle of Greek syntax that he discovered as affirming the New Testament teaching of the deity of Christ.

SHERIF, MUZAFER
1906–1988
Born in Turkey, Muzafer Sherif built a productive career as an experimental social psychologist. Upon receiving his master’s degree at Istanbul University, he continued his studies in the United States, earning a master’s degree at Harvard in 1932 and a PhD at Columbia in 1935. After spending the World War II years (1939–1945) in Turkey, Sherif returned to the United States as a postdoctoral fellow at Princeton and Yale. He then became a research professor of psychology at the University of Oklahoma and
later a distinguished professor of sociology at Pennsylvania State University. His tenure in these two rather different departments illustrates his unwavering commitment to social psychology as an interdisciplinary enterprise.

SHERIF AND NORM FORMATION
Sherif produced many creative studies, and his publications spanned five decades. He was most noted for three lines of research. The first was the focus of his doctoral dissertation, “A Study of Some Social Factors in Perception.” Inspired by the work of the French sociologist Émile Durkheim (1858–1917) and the British anthropologist Bronislaw Kasper Malinowski (1884–1942), Sherif recognized the importance of the process of norm formation in a group situation. The dynamics of this process occurred when individuals faced a recurrent situation in which they were interdependent. In one of his studies Sherif looked at people’s judgments of the extent of movement of a pinpoint of light. He noted that when a person sees a small light in an otherwise completely dark room, it appears to move even though it is stationary. This autokinetic effect provided a suitable setting since it was an ambiguous situation when estimations were made of how far the light moved, thus lending itself to a variety of judgments.

Sherif had subjects give their perceptions individually over 100 trials and then in subsequent sessions in group situations. When estimating individually, subjects tended to form their own personal reference scales, but when brought together in a group, they tended to converge in their estimations. This convergence was regarded by Sherif as the essence of norm formation, one of the basic forms of social influence. In a variation in design Sherif sought to demonstrate that norms formed in a group situation would carry over into a situation in which other group members were not present.

INTERGROUP STUDIES
The second line of research for which Sherif is responsible involved a series of intergroup summer camp studies. This series culminated in a 1954 study at Robbers Cave State Park, Oklahoma. There, twenty-two eleven-year-old boys faced tasks that divided them into groups. Those groups then competed vigorously for mutually exclusive goals and finally cooperated to achieve superordinate goals. The latter refers to goals that are highly desired by two groups but that can only be achieved through cooperation.

Groups grew into units with their own distinctive norms and status structure as a result of repeated interaction in situations of interdependence. When the groups interacted with antithetical goals, they formed negative stereotypes of each other and gave vent to hostility and aggression in many forms. Most importantly, when hostile groups interacted in a series of superordinate goals, hostility was diminished, and the stereotypes became more positive. Sherif’s interest in intergroup relations was undoubtedly influenced by the turbulent events he witnessed as a Turkish youth as well as the American psychologist and philosopher William James’s (1842–1910) 1906 essay “The Moral Equivalent of War” (1910).

SHERIF AND ATTITUDE CHANGE
The third line of research Sherif was responsible for initiating was his unique take on the subject of attitude change. His social judgment theory held that one’s reaction to a communication, in terms of positive or negative attitude change, would depend on where one placed the communication. Misplacing a communication in the direction of one’s own attitude, called assimilation, facilitated positive attitude change. Distortion of a communication away from one’s own attitude position was called contrast, and when that occurred, attitude change in the direction opposite to that advocated by the communicator was predicted. Ego-involvement and discrepancy were also important concepts in social judgment theory. As involvement increased, positive attitude change decreased. As discrepancy increased, positive attitude change increased up to the point of inflection and decreased beyond that. Sherif’s view was that it is more useful to think of an attitude as a series of zones (latitudes of acceptance, noncommitment, and rejection) than as a single point on a numerical scale. In connection with this theory, two innovative measuring instruments were devised, the own categories procedure and the method of ordered alternatives.

SHERIF’S OTHER CONTRIBUTIONS
Although Sherif is best known for his empirical contributions, he did have an overarching theory. That theory was centered on the concept of a frame of reference, conceived as the totality of external and internal factors operating at a given time. This concept was accompanied by a set of twelve propositions, as he outlined in his 1969 book published with Carolyn Wood Sherif. In that book he noted, “The more unstructured the external stimulus situation, the greater the contribution of internal factors” (Sherif and Sherif 1969, p. 62).

Another of Sherif’s contributions to social psychology had to do with the role of experimentation in the research process. For Sherif, experimentation came late in the research process, only after one had gained an intimate knowledge of the phenomenon under consideration. In this way Sherif believed one could be confident that his or her research would have a bearing on real world events. Sherif saw himself as committed to doing basic research, but the implications were there for anyone interested in applied research.
SHINTO

Shinto is the indigenous religion of Japan. Although its origins extend back into Japan’s prehistory, Shinto has undergone significant periods of development throughout the country’s history, and it continues to be an important part of Japanese culture.

ORIGINS AND HISTORICAL DEVELOPMENT

Although Shinto can be traced back to Japan’s Jomon period (c. 11,000–400 BCE), it was during the Yayoi period (c. 400 BCE–250 CE) that the key elements associated with its development—wet rice agriculture, fertility rituals, and stable, long-term communities—appeared. During this time, local shrines were established and many of the beliefs and practices seen in Shinto today came into existence. During the Kofun period (c. 250–592 CE), Shinto became associated with a large-scale process of political consolidation. Although there remained small shrines in local communities, large Shinto shrines were built at Ise and Izumo on the eastern and western sides of the central Japanese island of Honshu, reflecting the more centralized political structure that was emerging. By the early Nara period (early eighth century), the first written histories of Japan—the Kojiki (712) and the Nihon shoki (720)—included myths associated with Shinto that served to legitimize the imperial line and the leadership of the Japanese state. Primary among these was the mythic descent of the first Japanese emperor, Jimmu, from the sun goddess, Amaterasu.

The introduction of Buddhism into Japan from China around the middle of the sixth century also brought a new dimension to the development of Shinto. Buddhism, which had a much more extensive theology and culture (art, architecture, and literature) associated with it, came over time to coexist peacefully with Shinto, rather than to compete with it. The two religions—Shinto, with its connections to fertility and life, and Buddhism, with its theology reaching beyond the present world—grew to support one another. Beginning in the eighth century, Buddhist temples and Shinto shrines were often located together on the same site. In 743 the Shinto deity Amaterasu and the cosmic buddha Vairocana were officially declared to be two dimensions of the same reality. In the centuries that followed, the syncretistic relationship between Shinto and Buddhism continued to develop.

During the Tokugawa period (1600–1868), a shift away from Buddhism occurred, and a stronger connection to Confucian thought (introduced into Japan during earlier contact with China) developed. During this time, Shinto came to be used as a mechanism of support for political and social unity. This role of Shinto reached its peak during the Meiji period (1868–1912) and the pre–World War II and wartime portions of the Showa period (1926–1989), when Shinto branched off into Sect Shinto (retaining its local characteristics and Buddhist connections) and State Shinto (which became an official state religion and was used to instill a sense of loyalty to the country). Under State Shinto an Office of Shinto Worship (Jingikan) was established, and a system of national shrines was given official support and patronage. Reverence for the emperor, who was now considered to be a Shinto deity—“sacred and inviolable” in the words of the Meiji Constitution (1889)—and support for the Shinto concept of kokutai (body politic or national essence) was required in Japanese schools. Following Japan’s defeat in World War II (1939–1945), State Shinto was banned, the emperor was forced to renounce his divine status, and Shinto in large degree returned to its earlier pattern of local shrines and its connections with Buddhism. With key modifications, the religion continues in modern times to play a significant role in Japanese culture.

CORE BELIEFS AND PRACTICES

A central feature of Shinto lies in a belief in the existence of spirits or deities in nature known as kami. These spirits are usually associated with natural phenomena, such as a mountain, a waterfall, a large tree, or an unusual rock.

Donald Granberg

SHINING PATH

SEE De Soto, Hernando.
The surrounding area then comes to be considered sacred, and a shrine (jinja) is erected there. Various rituals are performed at the shrine, among the most important being food offerings and rites of purification. In the beginning, the shrines were strictly local in character, and agricultural fertility was a central purpose of the rituals performed there. Annual shrine festivals (matsuri) were events of great importance in the local community. Over time, certain shrines came to be thought of as connected with particular needs and serve as places to pray for human fertility, success in business, or even (in modern times) success in passing college entrance exams. Some shrines assumed regional significance. Other shrines—as mentioned in the preceding section—reflected a larger, national purpose.

Over time also, shrine architecture came to follow certain basic styles or types. The earliest shrines (exemplified today by the great Ise Shrine dedicated to Amaterasu) were constructed of unpainted wood, but after the introduction of Buddhism, many shrines were painted a brilliant vermilion red, displaying the Chinese Buddhist influence. Large gateways (torii)—also of varying styles—mark the entrance or approach to a shrine. Other important shrine features include stone dogs (komainu) guarding the shrine entrance, a place of purification (chozuyu) where worshippers stop to wash their hands and rinse their mouths prior to approaching the main shrine building, the main sanctuary (honden) where the kami is believed to reside, the collection box (saisen-bako) where money is thrown to express gratitude to the kami, and a special bell (suzu) connected to a rope, which worshippers ring to announce their arrival.

In addition to participation in the annual shrine festival, people also visit shrines on national holidays such as New Year’s (shogatsu) or the summer Bon festival (obon). Most Japanese are married in a Shinto wedding ceremony, and there are other shrine ceremonies celebrating various life passages, such as the first shrine visit for a newborn child (batu-mijamairi) or national Coming-of-Age Day (seijin-no-hi) for twenty-year-olds, which takes place on January 15. Finally, many traditional Japanese sports (sumo, for example), as well as other forms of traditional culture, have their roots in Shinto.

**IMPORTANCE TODAY**

Since the end of World War II and the banning of Shinto as an official state religion, Shinto practice has focused primarily on its role as an aspect of traditional culture. More than 100,000 shrines existed in the country in 2003, ranging from small neighborhood shrines to large shrines of national significance. Japanese tourists flock to the famous shrines in historic cities like Kyoto and Nara. National holidays and family rites of passage, as well as matsuri, are celebrated at local or neighborhood shrines. It remains common for people to have a small Shinto family altar (kamidana, “god shelf”) located above the entrance to their homes. Although occasional controversies surface regarding holdovers from Shinto’s earlier role as a state religion—the periodic controversy, for example, surrounding the Yasukuni Shrine commemorating the war dead in Tokyo—Shinto, for the most part, is a colorful and happy form of religious expression, the darker side of human existence being left to Buddhism with its funeral rituals and ideas concerning the next life. Most Japanese consider themselves, at some level at least, adherents of both religious traditions.

**SHIPPING INDUSTRY**

Shipping has been a major means of transporting bulky commodities since prehistoric times; the stones used to construct Stonehenge were moved by sea and those used in the Egyptian pyramids came by barge down the Nile. The shipping sector was central to the economies of many early Mediterranean civilizations and, for example, provided the bulwark for Minoan power. Shipping became entwined with early financial institutions as individuals in Athens financed the long lead times between investments and returns, although it was not until the ninth century that the first mercantile bank was established. The Roman Empire and those in China depended extensively on their commercial shipping for trade and to bring the fruits of distant domains back to the core regions.

The role of shipping was subsequently a facilitator in the growth of the more explicit maritime powers after the fall of Rome. The Vikings exerted their influence from Greenland to Russia and down into modern Turkey almost exclusively through their control over trade and the quality of their military vessels. Commercial shipping has
always been entwined, because of the lags and uncertainties involved in voyages, with insurance and banking; and the emergence of sophisticated finance markets in Italy in the fourteen and fifteenth centuries led expansions in Mediterranean maritime activities. The Spanish financed their sixteenth-century European wars more directly with gold brought back by galleons from their colonies in the New World.

Subsequently the Dutch and British empires were founded upon powerful navies that complemented and protected extensive civilian trading fleets. In particular, in the early phases of the Industrial Revolution when land transportation remained difficult, maritime trade allowed new export markets to be served and new sources of raw material to be exploited. Many of the major seaports in Britain, such as Liverpool and Bristol, and in the southern states of the United States, such as Charleston, South Carolina, grew on the back of the triangular trade routes carrying manufactures, raw materials, and slaves that linked Europe, Africa, and the Americas. In Asia, the growth of maritime trade in spices and commodities using oceangoing junks underlay the prosperity of Indian and Chinese coastal areas. In addition to the transportation role, the shipping industry made direct contributions to production in the fishing and whaling industries that grew to feed and supply industrializing nations with food and oil.

The advent of the steam engine made for more reliable and safer shipping services but also, in the context of its linking with the railways that provided feed and distribution service to ports, increased the potential markets that could be served. Technological developments (such as refrigerated ships and steel hauls), the demands for new products (such as oil) in the late nineteenth century, and the emergence of new technologies (such as the container and the mega-ships) in the late twentieth century have helped to maintain the momentum of the industry.

Much of the emergence of the scale of the modern shipping industry can also be traced by the impetus given it by World War I and World War II that not only required a large mercantile marine for military logistics reasons, but also subsequently dumped a stock of vessels on the market that allowed entrepreneurs to build up commercial fleets at relatively low capital costs and with suitable discharged sailors available to man them.

In the early twenty-first century the international shipping industry carries about 90 percent of global trade by weight. While much of this involves transoceanic movements, short-sea shipping plays an important role in many large freight markets. Shipping also provides important ferry and passenger services. In 2005 globally there were approximately 42,200 registered ships with a combined tonnage of nearly 600 million gross tons. Of these more than 20,000 were general cargo vessels, 6,100 bulk carriers, 3,200 container vessels, 11,300 tankers, and nearly 5,700 passenger ships. This pattern reflects the changing technologies and production priorities of the larger supply chain (e.g., the advent of containers from the 1960s and just-in-time production) and the types of commodities carried (e.g., the increased demands for oil.) The global fleet is registered (flagged) in a variety of countries with registration often depending on local tax structures rather than the locations of shipping activities. The widespread registration under “flags-of-convenience” reflect these financial considerations.

Cargo activities can be divided between unscheduled, tramp shipping, which involves the leasing of a ship for a particular trade, and liner activities. The latter provide regular sailings and carry partial loads. Liner activities have existed from the 1870s when steamship technology allowed for reliable scheduling of sailings and often involved some form of cartel arrangements between shipping companies. These have evolved through “conferences” that coordinate services and rates, allocate capacity between members, and offer loyalty discounts for specific, often unidirectional, routes; through “consortia” from the 1970s whereby some conference members offered joint services; and through alliances that engage in cross-route rationalization and do not issue a common tariff. These tendencies toward a degree of collusion are often seen as important to ensure that regular services can be provided and that shipping companies can make a reasonable return on their large capital investments in what would otherwise be an excessively competitive market. Economic regulatory bodies, especially in the United States, however, have regularly been concerned about the potential monopoly power they might create.

Policy challenges remain, and many extend beyond conventional market regulation. Shipping has always been closely associated with the environment. Classical times saw Greece being denuded of trees to build fleets and a similar fate nearly befall the British oak tree in the eighteenth century. From a different perspective, it was shipping that brought the Black Death pandemic to Europe in the fourteenth century that killed one-third of the population. In the early twenty-first century, the high visibility of major maritime disasters, especially when there are major adverse environmental implications, poses challenges, as does the concern that ships or their cargos may form the basis for terrorist actions. The problems are seen to be growing as scale economies stimulate the use of larger vessels (e.g., post Panamax ships), which have the potential for inflicting massive environmental damage in the event of an accident, and as the general growth in world trade, both in aggregate and in the diversity of nations involved, makes policing the shipping industry more complex. The growth in the number of vessels operating under flags of convenience adds to these difficulties.
In order to confront the more traditional challenges posed by the shipping industry, as well as the newer ones, industry is heavily regulated at several levels—most notably at the global level by the United Nation’s International Maritime Organization (IMO) that oversees safety and environmental matters and the International Labor Organization (ILO) that focuses on labor standards in the shipping industry. National governments control movements within territorial waters, register vessels, and regulate within their antitrust policies the nature of the services that can be used for their trading activities, for example, the particular features of any cartel arrangements. But shipping is also regulated in a de facto way by local governments that often own and, inevitably, control ports that form the terminals for shipping operations. Integrating the roles and activities of this hierarchy of institutions so that effective maritime policies can be achieved has often proved elusive.

SHKLAR, JUDITH
1928–1992

Judith Nisse Shklar was Cowles Professor of Government at Harvard University and one of the most influential political theorists of the late twentieth century. Though her studies were wide-ranging in focus, her work centered on the problems of cruelty, exclusion, oppression, and fear in liberalism.

Born in Riga, Latvia, to Jewish parents, Shklar was still fairly young when her family fled Europe to avoid Nazi persecution. Perhaps accordingly, her first major work, After Utopia: The Decline of Political Faith (1957), wrestles with the intellectual legacy of twentieth-century totalitarianism. In a time when the political application of comprehensive ideologies has led to so much horror, is there any future for the discipline of political theory? Shklar found it unlikely that its future would look like its past; political theory had little chance of returning to the high levels of hope and optimism that had once marked it, particularly during the Enlightenment. In this postfa-

natical age, she argued, political philosophers would do best to take up the gauntlet of intellectual history and avoid future entanglements with “isms.” Shklar thus articulated an argument that would mark her career: Philosophy needs to separate and extricate itself from ideology.

Shklar herself found much to defend in classical liberalism, which she described in her seminal essay “The Liberalism of Fear” as resting on the proposition that “every adult should be able to make as many effective decisions without fear or favor about as many aspects of her or his life as is compatible with the freedom of every other adult.” For Shklar, unlike others who find more aspiration in the liberal framework, liberalism has no positive, moral aim outside this basic commitment to political and social freedom.

In that sense, Shklar’s liberalism rests upon a pessimistic or skeptical sensibility. Her version of liberalism does not aim for the best; rather, it is concerned with averting the worst. And the worst, for Shklar, is the kind of partisan injustice and cruelty that might also be called political evil.

Shklar’s dedication to this kind of “barebones liberalism,” as she called it in her second and favorite book, Legalism: Law, Morals, and Political Trials (1964), is evident throughout her corpus. Even in her treatments of individual thinkers—she composed full-length books on the political theories of Georg Hegel, Montesquieu, and Jean-Jacques Rousseau—Shklar remained invested in supporting liberalism but divesting it of any perfectionist associations.

Any account of Shklar’s life and works would be remiss not to mention that she was one of the first women to achieve success in the field of political philosophy—and, in fact, the first woman to serve as president of the American Political Science Association. Though Shklar acknowledged that her career, especially in its earliest days, had been made more difficult by the pervasive sexism of the age, she resisted being classified as what she called a “real feminist.” To identify herself with a collective ideology, she argued, would be to undermine her own intellectual project.

SHOCKS

In economics a shock is an unexpected change in the economy or a component of the economy. The hypothesis of rational expectations holds that individuals will incorporate all available and relevant information into their decision-making processes. From a behavioral standpoint, shocks are important in that they alter individuals’ behaviors by altering the information that goes into their decision-making processes. This alteration in behaviors in turn has economic consequences.

Because of people’s ability to anticipate changes in the economy, shocks are difficult to measure. In the past, changes in economic measures have been taken as proxies for shocks. For example, if inflation increased from 3 percent to 4 percent, economists would say that a 1 percent positive shock to inflation had occurred. This approach is not entirely satisfactory as the greater the ability of individuals to anticipate the change, the less the change represents a shock. For example, a rise in the price of gasoline from $2.50 to $2.75 would have represented a shock of $0.25 only if people expected that the price of gas would remain at $2.50. If people had expected the price of gasoline to rise from $2.50 to $2.75 and the price of gas actually did rise from $2.50 to $2.75, then the change in the price would have represented no shock at all. If, however, people had expected that the price of gas would rise from $2.50 to $2.75 but in fact the price only rose from $2.50 to $2.60, then the change in the price of gas would have been $0.10 and the shock would have been negative $0.15. That is, people would have anticipated an additional $0.15 price increase that never materialized. The difficulty in measuring shocks lies in the difficulty of knowing how much of a change in an economic measure was anticipated and how much was unanticipated.

While an unanticipated change in any economic measure can be described as a shock, economists give most attention to inflationary shocks (unanticipated changes in inflation), production shocks (unanticipated changes in the growth rate of real gross domestic product [RGDP]), and leading shocks (unanticipated changes in leading economic indicators). Positive inflation shocks represent unanticipated price growths and lead to reduced real wages and a slowdown in consumption. Positive production shocks represent unanticipated increases in real economic activity and can lead to an unanticipated reduction in inflation and growth in real wages. Leading economic indicators typically change direction prior to a turning point in business cycles. Unanticipated changes in leading economic indicators can indicate the approach of a turning point in the business cycle.

Methods for measuring economic shocks require multidimensional panel forecasts. A multidimensional panel forecast data set is a set of forecasts generated by multiple forecasters over multiple time periods and forecasting at multiple time horizons. For example, forecasters A, B, and C (multiple forecasters) will forecast inflation for the year in January, again in February, again in March, and so on (multiple horizons), and they will repeat this every year over a number of years (multiple time periods). Assuming that economic forecasters are rational, the forecasts can be taken to be reasonable measures of people’s expectations about the future, and even if the forecasters are biased, the biases can be filtered out such that estimates of economic shocks can be extracted from what is left. Measures of shocks and volatilities of shocks can be extracted from multidimensional panel forecasts via econometric methods.

The volatility of shocks is the variance of the shocks hitting the economy over time. For example, the economy may experience a sequence of large positive and negative shocks that mutually cancel each other out such that the net shock over the period is zero. However, the volatility of the shocks over the period will be nonzero as the shocks rose to positive levels then fell to negative levels. Consumer and investor uncertainty is a function of both shocks and the volatility of shocks. Uncertainty in turn impacts economic growth. The more uncertain consumers are about the future, the less likely they are to engage in transactions and so the slower is economic growth. Similarly the more uncertain investors are about the future, the less likely they are to invest and so the slower is economic growth. Studies indicate that the relationship between shocks and volatility is asymmetric. Negative shocks tend to be associated with greater volatility than positive shocks. This is typically interpreted as individuals regarding bad news of a given magnitude as being more influential on their decisions than is positive news of the same magnitude.

Susan J. McWilliams
SHORT PERIOD

Economists measure periods in units of economic time. In the market period, time is compressed so that supply cannot vary. In the short period (SP), time occupies an interval in which fixed investments cannot change; in the long period, time is sufficient to allow all inputs to vary. Fixed investments include specialized skill and ability, machinery, and organizational structure. In the SP, one can only mix and match fixed investment to meet changing demand and supply conditions. Alfred Marshall (1842–1924), the reigning British economist of his day who is credited with these views, was aware that no sharp line of demarcation could be drawn between the short and the long periods ([1929] 1982). A day gives an intuitive feel for the market period. For the SP, one considers not only the given supply of, say, bread for that day, but goes back to the planting of wheat, which started approximately a year before, and the expected prices set at that time. The expected price may reach its normal values from two months to a year, bracketing the SP.

One problem with the SP is whether fixed investments should extend beyond the production period. Plough or die-casting equipments may last for only one production period, and the stock of capital should reflect the life of such short-lived equipment. If the adjustment spreads over time based on available price signals, then the SP definition is in jeopardy. Alternatively, one can deduct values from equipment in the previous period. Another problem in the SP is that various industries take different time intervals to produce a product with the same plant units, making it impossible to have an aggregate SP for the whole economy. The preeminent economist John Maynard Keynes (1883–1946) answered these problems by using the concept of prime cost, which is the sum of factor and user costs in defining income and its components of savings and investments; by using the concepts of exante vs. ex post for equating saving and investment; and finally by settling on the more logical concept of national income identity.

Post-Keynesians have many interpretations of the Keynesian short period. A counter long-period view is that long-period expectations are not realized yet. One argument is that Keynes's view is a special case of the classical system. Richard Kahn's (1989) view that short run average cost was constant with a reversed L-shape up to a maximum level of output seems to counter Keynes's view of a Z curve in chapter 3 of the General Theory. On the special case characteristics, Lawrence Klein (1966) stated that the SP Walrasian (named for the French economist Léon Walras [1834–1910]) equilibrium might not exist in the Keynesian model because of interest inelastic investment or very high interest elastic demand for money due to market imperfections. Marshall's protégé Arthur Pigou (1877–1959), in correspondence with Keynes, was the first to draw a reversed L-shape labor supply curve for the SP. From the dominant textbook perspective, Keynes's SP solution made output and employment depend on investment through a multiplier and made the equality between saving and investment follow from two logical premises—income is the sum of consumption and investment, and saving is income less consumption. Keynes appears to fix all capital stock for the whole economy in the SP, analogous to Marshall's fixing production units for a single industry. Although Keynes dealt with liquidity preference and marginal efficiency of capital schedules that vary with long-term expectation, he defined SP expectation as a day and restricted long-period expectation to the view of mass psychology, which plays out in three months to a year, corresponding to Marshall's market period and SP, respectively.

Following Keynes, John Hicks (1904–1989) created a temporary (sequential) equilibrium model that reflected Keynes's SP. Prices are determined in the market period, Monday, and production varies during the rest of the week to meet varying market conditions. The past week, $t - dt$ to $t$, or the future week, $t$ to $t + dt$, is an infinitesimal period during which production can change. The long period is a link of various Mondays and weeks together.

For modern policy analysis, the SP equilibrium is reflected in a downward sloping Phillips curve at a position of nonaccelerating inflation rate of unemployment (NAIRU). For the monetarists and the new classical school, adjustments for SP differences between actual and expected prices enables convergence of the aggregate SP supply schedule to the long-period natural level where desired expectations are fulfilled. Robert Lucas and Thomas Sargent (1981), who extended the Walrasian and Marshallian concepts of price taking to the case where price provides information, were not concerned with long- and short-run characterizations, but with drifts in structural parameters of their models. The modern literature also developed an SP non-Walrasian equilibrium concept that depends on current prices and the expectation of...
future prices based on past and current prices. Thus the economic agents are able to carry out all their preferred actions in current markets.

SHORT RUN

The term short run refers to a period of time in which at least one factor (input) of production cannot be immediately modified. This concept determines exactly how a firm’s decision-making is constrained. Factors of input may be constrained by past decisions or a decision that cannot immediately be implemented. The short run contrasts with the long run, in which all input factors that can be variable are variable. The short run does not specify any exact length of time, such as three months or one year. The short run can be five minutes or five years, depending on the exact characteristics of the fixed factors. Examples of circumstances that would place a firm in a short-run situation include but are not limited to: contracts that cannot be broken on rented machinery, the time required to build a bigger factory, rental agreements on factory space, the time required to purchase and assemble additional machinery, and the time required to find a renter for owned capital.

In the perfectly competitive model, the short run constrains firms to change only the amount of variable costs, typically the amount of labor employed. In the classic example, a firm can increase (decrease) production only by increasing (decreasing) its labor force. The amount of capital is fixed in the short run because the rental or purchase of large machinery and factory space requires long-term contracts that are not immediately revised. Contrasting this to the long run, labor is still variable, but now each individual firm has the option to purchase more capital or to not renew contracts and employ less capital.

In the short run, a firm will choose the level of variable inputs that maximizes its profit taking given its level of fixed inputs. The profit-maximizing output level may be chosen at zero, implying the short-run shutdown decision. In this case when the price at which a firm can sell its goods lies below the average variable costs of the firm, the firm would lose money on each additional unit of good that it produces, leaving it better off not to produce at all. A firm may not exit the industry in the short run, however, because of existing fixed costs. Once all fixed costs become variable, the firm has entered the long run, and is no longer in the short run. This gives the firm more opportunities to lower costs and increase profits by altering its inputs to achieve the most efficient production techniques. If the firm is unable to become profitable in the long run, it has the long-run option to exit the industry.

There are short-run and long-run versions of supply, demand, and the entire family of cost curves (marginal cost, average cost, total cost). It is important to recognize that in the short run, a firm has variable costs and fixed costs, represented by two separate curves. In the long run, all fixed costs become variable, eliminating the fixed cost curve and causing the variable cost and the total cost curves (and thus the corresponding average variable and average total cost curves) to collapse into one total cost and average cost curve. Typically, the short-run version of each curve is less elastic than its corresponding long-run version.

Jacob Viner presented these concepts in his 1931 work, “Cost Curves and Supply Curves,” which formalized the graphical and analytical analysis of short-run and long-run cost curves. This work is visible in the economics textbooks of the early twenty-first century as the graphical representations of markets and firms that are used to determine market equilibrium and firm behaviors.

In the field of macroeconomics, Milton Friedman (1912–2006) developed short-run and long-run concepts...
differentiated from one another with respect to expectations. In the short run, expectations about the future are not fully realized, and conversely in the long run, expectations are fully realized. For example, Edmund S. Phelps (b. 1933) and Friedman provide a distinction between the “short-run” and “long-run” Phillips curves. The Phillips curve, originally formulated by the New Zealand economist A. W. H. Phillips (1914–1975), displays the inverse relationship between unemployment and inflation. In the short run, expansionary monetary or fiscal policies will raise nominal wages as the demand for labor increases. These same policies will also have the effect of raising the overall price level, resulting in smaller real wage changes relative to the nominal wage change. Workers will eventually realize the inflationary effect on their real wages and insist on wage changes that keep pace with inflation. Those who entered the labor force because of higher nominal wages will exit once they realize that real wages are no higher than before the policy modification. The result is that in the short run, workers may supply more labor in response to expansionary policies in the absence of fully realized expectations, but in the long run, once expectations of price inflation have adjusted, unemployment will increase back to the previous natural level, while nominal prices and wages remain at their higher levels because of the original expansionary stimulus. This results in a deviation from the traditional Phillips curve, which Friedman refers to as the expectations-augmented Phillips curve. The faster the worker’s expectations are realized, the sooner the short run transitions into the long run, and the less effective expansionary policies will be.

In conclusion, the short run and the long run may be summarized as follows:

- **Short run**: Some inputs variable, at least one fixed. Firms can choose a level of production only by changing the amount of a variable input. Choosing an output of zero implies the shutdown decision. New firms do not enter the industry, and existing firms do not exit. Supply, demand, and cost curves are less elastic (more inelastic).
- **Long run**: All inputs variable, firms can enter and exit the marketplace. Supply, demand, and cost curves are more elastic.

**SHTETL**

The *shtetl*, Yiddish for “small town” (plural *shtetlekh*), was the archetypal eastern European Jewish community for over half a millennium. Moreover, it emerged during the twentieth century as a social paradigm of Jewish communal life and became the subject of extensive Jewish memory practices in the wake of the Holocaust. As early as the thirteenth century, Jews settled in small towns in Poland, where they played a central role in the local economy as merchants, artisans, and managers of property owned by the aristocracy. Eventually these towns, in which Jews sometimes comprised the majority population, stretched the length and breadth of eastern Europe. Here the Jewish population surged during the eighteenth century, making shtetlekh home to the majority of world Jewry for over a century.

Jewish shtetl life received little analysis until Jews began leaving these towns in large numbers during the latter half of the nineteenth century as a result of urbanization and immigration. The shtetl figured centrally in early works of modern Yiddish literature—most famously by Sholem Aleichem (Sholem Rabinovitch, 1859–1916)—many of which offered astute critiques of traditional Jewish mores and provincial society through satire. The early twentieth century witnessed a new interest in traditional eastern European Jewish life among modernizing Jews, prompting early ethnographic efforts to collect folklore in both the shtetl and the rural village (Yiddish: *dorf*). The most famous early example was the 1912–1914 expedition in Ukraine led by S. Ansky (Solomon Rappoport, 1863–1920), who subsequently drew on the materials collected to write *The Dybbuk* from 1912 to 1917, the best known work of modern Yiddish drama.

During the interwar years, scholarly efforts to study shtetl life were organized by the YIVO Institute for Jewish Research in Vilna, Poland (now Vilnius, Lithuania), and researchers in state-supported institutes in the Soviet Union. These undertakings included grassroots projects, such as a pamphlet published in Minsk in 1928, which exhorted amateur folklorists, “Forsht ayer shtetl” (Research your town). Individual ethnographies, memoirs, literary works, and journalistic accounts of shtetl life also appeared during this period in Yiddish, Hebrew, Polish, Russian, German, and other languages.

Following the genocide of European Jewry during World War II (1939–1945), many former residents of
shtetlekh initiated efforts to memorialize their own local histories, customs, and murdered townsfolk, most notably by compiling *yiker-bikher* (communal memorial books). At the same time, American anthropologists undertook a major project to write a composite study of prewar eastern European Jewish life based on research from a pioneering wartime “anthropology-at-a-distance” project overseen by Margaret Mead (1901–1978) and Ruth Benedict (1887–1948). The resulting book, *Life Is With People* (1952), quickly became the standard work in English on shtetl life. As folklorist Barbara Kirshenblatt-Gimblett has observed, this book’s approach offers an idealized, paradigmatic vision of the shtetl—timeless, uniform, insular—that is as problematic as it was appealing in the aftermath of the Holocaust. The impact of *Life Is With People* has been extensive, influencing, among other works, *Number Our Days* (1978), anthropologist Barbara Myerhoff’s (1935–1985) study of elderly American Jewish immigrants from eastern Europe. More recently, return travel to shtetlekh has been the subject of ethnographic films (e.g., Marian Marzynski’s *Shetel* [1996]) and studies of Jewish memory practices.

**SHYNESS**

Shyness can be defined by the presence of anxious reactions, excessive self-consciousness, and negative self-evaluation in response to real or imagined social interactions to the degree that it produces enough discomfort to interfere with and inhibit one’s ability to perform successfully in social situations and also to the extent that it disrupts one’s personal and professional goals. The symptoms of shyness can be affective (e.g., heightened feelings of tension and anxiety), physiological (e.g., racing heart, dryness of the mouth), cognitive (e.g., heightened self-consciousness and excessive thoughts of critical self-evaluation), and behavioral (e.g., increased interpersonal distance, inhibited verbal participation, and lack of eye contact). The number of adults who consider themselves to be chronically shy (e.g., shy their entire lives) is approximately 40 percent (Carducci 1999).

Subtypes of shyness include situational shyness (temporary shyness triggered by specific situations such as meeting a famous person), shy extroversion (outgoing appearance coexisting with a high degree of anxiety and negative self-evaluation, often experienced by entertainers), and transitional shyness (an extended period of shyness brought on by life changes such as moving to a new town). Introversion is not considered a subtype of shyness. Although shyness and introversion are similar in their overt expressions of behavior, they differ in their underlying motives. Introverts do not necessarily fear social situations, but simply prefer more solitary activities. Shy individuals, like extroverts, prefer social activities but are restrained in their participation by the experience of shyness. This approach-avoidance conflict is a source of distress for shy individuals.

The characteristic features of shyness include an excessive degree of self-consciousness, negative self-evaluation, and negative self-preoccupation. Shy individuals also demonstrate a slow-to-warm tendency characterized by an extended period of adjustment to social situations, especially those that are novel. Situational shyness is the transitory experience of shyness that can be triggered by a variety of situations, the most frequent being interactions with authorities, one-to-one interactions with members of the opposite sex, and unstructured social settings.

The most frequently used measure of shyness is the Revised Shyness Scale (RSS). The RSS contains fourteen items assessing the three principal dimensions of shyness: affective/physiological (e.g., “I feel tense with people I don’t know”), cognitive (e.g., “I feel painfully self-conscious when I am around strangers”), and behavioral (e.g., “it is hard for me to act natural when I am meeting new people”). The RSS uses a five-point Likert scale, with responses ranging from 1 (“very uncharacteristic or untrue, strongly disagree”) to 5 (“very characteristic or true, strongly agree”). Scores on the RSS demonstrate acceptable test-retest reliability and validity by correlating highly with other measures of shyness, social avoidance, and interpersonal difficulty.

Distinctions have been made between shyness and other socially related constructs. Like shyness, embarrassment is characterized by heightened self-consciousness, but unlike shyness, embarrassment includes feelings of guilt and is a response that occurs after an inappropriate social response in the presence of others. Individuals do not experience embarrassment prior to the performance of an inappropriate response or when others are not present. In contrast, the affective (e.g., anticipatory feelings of anxiety), cognitive (e.g., assuming one’s comments will be judged unfavorably by others), and behavioral (e.g., not approaching others) responses characteristic of shyness can occur prior to the actual performance and in the
absence of others (e.g., before entering a social situation). Social anxiety, like shyness, involves anxiety and self-critical evaluation in novel social settings, but to a greater degree: Individuals affected by social anxiety have greater difficulties in social situations (e.g., parties) and therefore may avoid them, but there is little disruption in other social aspects of their public lives (e.g., riding on public transportation, eating in a restaurant, or going shopping). Social phobia, which is experienced by approximately 8 percent of the population, is a clinically diagnosed psychiatric condition that, like shyness and social anxiety, involves feelings of anxiety and excessive critical self-evaluation, but to such a greater degree that it has a much more pervasive and disruptive influence on one's ability to participate in everyday situations.

Causes of shyness can be psychological (e.g., the result of family dynamics), biological (e.g., determined by hormonal and neurotransmitter levels), genetic (e.g., inherited temperament), neurological (e.g., bed nucleus of the striate terminals), or cultural (e.g., prioritizing the individual over the collective). The evolutionary benefits of shyness include cautionary behavior in novel and potentially threatening situations and the facilitation of social exchange and cooperation through the reduced tendency for self-serving expression. The personal costs of shyness include increased personal blame for interpersonal failures, loneliness, and substance abuse; the social costs, particularly for males, include less stable marriages, career delay, and lower levels of career advancement.

Interventions available for dealing with shyness include informational Web sites, self-help books, self-directed programs, and structured clinical programs. Different treatment approaches are utilized depending on which component of shyness is targeted. Approaches for dealing with the affective component of shyness tend to focus on the reduction of bodily arousal, such as progressive relaxation techniques and biofeedback. Approaches for dealing with the cognitive component of shyness typically emphasize cognitive modification, such as revising self-perceptions, altering attributions, and adjusting expectations for defining success in social situations. Approaches for dealing with the behavior component of shyness emphasize the acquisition and development of social skills, such as strategies for approaching others, techniques for initiating and maintaining conversation, and procedures for entering ongoing conversations. Structured clinical programs typically involve combining elements from all the approaches, such as cognitive modification to identify which situations produce the most critical self-evaluations and structured role-playing exercises within the context of systematic desensitization to reduce anxiety, teach appropriate behavioral responses, and build self-confidence. An emerging, controversial view of shyness links it to more serious psychiatric conditions such as social phobia and emphasizes its treatment with prescription drugs, such as those based on selective serotonin reuptake inhibitors (SSRIs).

SIBLING RELATIONSHIPS

Sibling relationships are the longest lasting relationships of most people’s lives, and about 85 percent of all people have at least one sibling. Studies by researchers such as Judy Dunn, Victor Cicirelli, Wyndol Furman, and Susan McHale have contributed to our understanding of how sibling relationships develop from early childhood to adulthood, and how siblings influence each other. Research has focused on four broad areas: development of the relationship across the life course, the links between sibling and other family relationships, the impact of siblings on individual health and well-being, and the ongoing discussion of why siblings are so different.

Sibling relationships begin the day the second child arrives, and sometimes even earlier as parents talk about the arrival of a new baby. Judy Dunn and Carol Kendrick (1982) used interviews and in-home observations of mothers, firstborns, and infant siblings to understand why some sibling pairs develop relationships that are warm and supportive while others develop relationships that are hostile and conflictual. Their research, along with other studies, finds that a positive sibling relationship is more likely to develop when parents include the firstborn child in care of the baby and when they talk about the new baby as a person with needs and feelings just like their “big sister or brother.” At the other end of the life span, researchers...
such as Victoria Bedford, Victor Cicirelli, and Ingrid Connidis have demonstrated that social support is an important function of sibling relationships in adulthood and that childhood rivalries can reemerge when siblings spend more time together as adults. More recently, research is growing on siblings during adolescence and early adulthood. For example, Katherine Jewsbury Conger, Chalandra M. Bryant, and Jennifer Meehan Brennem (2004) used observations of sibling interactions and information reported by siblings to explain the changing nature of the sibling relationship in adolescence and the implications for social support in adulthood.

Parents are clearly recognized as important figures in the lives of young children, but for many, siblings are also important. Older siblings play many roles as playmates, teachers, role models, advisors, therapists, friends, and even bossy babysitters. Younger siblings play complementary roles as playmates, students, advice seekers, competitors, friends, and unwilling participants in activities devised by helpful older siblings. In fact, studies of cultures around the world find that four- and five-year-old siblings in some societies begin teaching their younger siblings as early as two and three years of age about language and proper behavior (Zukow 1989). Thomas S. Weisner (1989) presents a theoretical framework that takes family relationships and culture into account in explaining the unique contribution of siblings to social, emotional, and cognitive development. Cicirelli (1995) provides a comprehensive review of the varied theoretical and methodological approaches that researchers have used to study the association between parent-child and sibling relationships and the link between sibling relationships and those with friends and classmates. Laurie F. Kramer and Amanda K. Kowal (2005) report that positive behaviors between firstborns and their friends in early childhood are related to positive relationships with their younger siblings in childhood and early adolescence. Kramer's research on resolving conflict between siblings will be of particular interest to parents.

The parents' marital relationship is another important factor in the lives of siblings. Research by Clare Stocker and others reports that spousal conflict is related to conflict between siblings and can interfere with siblings' ability to develop a positive relationship. Other research finds that some siblings bond more closely during difficult times such as a divorce or death of a parent. And research on stepfamilies finds that sibling relationships often suffer when parents divorce and remarry. Remarriage also adds the complexity of half-siblings and step-siblings.

Evidence is accumulating that siblings can promote competent behaviors as well as encourage problem behaviors. A special issue of the Journal of Family Psychology (December 2005) was devoted to research on siblings, and the studies demonstrate the exciting new advances made in this area. The editors, Laurie Kramer and Lew Bank, selected eighteen articles designed to "illustrate the ways in which sibling relationships serve as important contexts for both individual development and family functioning" (p. 483). Many of the studies use sophisticated statistical analyses that allow social scientists to examine sibling relationships within families across multiple points in time. These studies, conducted with a broad range of ethnically diverse families, demonstrate the increased appreciation for the importance of siblings' roles in family life and individual development. Interested readers will also want to refer to Frits Boer and Judy Dunn's 1992 book, Children's Sibling Relationships: Developmental and Clinical Issues, which provides a summary of clinical and developmental issues, including the impact of a sibling's illness or disability on individual development and sibling relationships.

One frequently asked question is why siblings are so different if they grew up in the same family. The ongoing debate centers on nature (a person's genetic makeup) and nurture (shared and nonshared experiences in the family such as parenting and other social settings). The field of behavior genetics uses comparisons between twins, full siblings, and adoptive siblings to explain individual similarities and differences in personality and behavior (Dunn and Plomin 1990; Lytton and Gallagher 2002). One example illustrates why there are no easy answers to this ongoing debate. Everyone can understand why identical twins (monozygotic, or conceived with one egg) are similar because they share 100 percent of their genetic material, so if differences are observed they are the result of the environment such as experiences with parents and friends. However, their environment also is likely to be more similar because these twins are the same sex and arrive at the same time in the family. Fraternal twins (dizygotic, or conceived with two eggs) also arrive in the family at the same time but share only about 50 percent of their genes and they may be the same or opposite sex. For these siblings, some factors are pushing them toward similarity and others toward difference. Full siblings (the most common variety) also share about 50 percent of their genetic material, but each sibling arrives at a different point in the family's life. Even though they all live in the same family, the experiences of one sister may be quite different from those of her sister or brother.

Differential parental treatment has been identified as one factor that explains why siblings in the same family might be so different (McGuire 2001). Parents, and most children, agree that parents should treat siblings differently because of age, sex, temperament, and other individual characteristics. However, if parents play favorites and the siblings feel the treatment is unfair, then there can be negative consequences. Several researchers (e.g., Gene...
Brody, Katherine Conger, Shirley McGuire, Susan McHale, and Robert Plomin have found that differential parental treatment may be related to negative relations between siblings, child behavior problems, and conflictual family relations. Moreover, siblings can also influence the parenting behaviors. The exploration of shared and non-shared environments as explanations for sibling similarities and differences continues to be a promising area for research.

SIGNALING MODELS
SEE Screening and Signaling Games.

SIGNALS
The word signal comes from the Latin word signalis, meaning “sign,” and from the Late Latin word signalis, meaning “of a sign.” A signal is an event, message, activity, or, generally, any means of communication that encodes or transmits a message or some information between at least two parties, the sender and the receiver of the message.

In economics, a signal is a means by which one party (the agent) conveys some meaningful information about itself to another party (the principal). The action of sending a signal is called signaling. In business, a signal is a means by which a firm conveys to the market (investors, financial analysts, banks, bondholders, stockholders, and all stakeholders) information about its current position and future prospects.

In a perfect market, all information is accessible to all at zero cost and simultaneously. However, markets in reality are not perfect and manifest a deviation from perfect information called asymmetric information. In some economic transactions, the participants have different access to information pertinent to their decision-making: One party has more or better information than the other, and
Sikhism

this inequality of information access disrupts normal market behavior. Michael Spence (1973, 2002) suggests that two parties with different exposure to needed information could overcome this problem of asymmetry by having one party send a signal to the other, revealing some pertinent information. The receiving party could interpret this signal and adjust their behavior accordingly. Interpretation, of course, is subjective and can lead to erroneous inferences. Thus, there is need for a lot of caution in signal interpretation.

There are types of sellers who usually have better information than buyers, such as used-car dealers, salespeople, mortgage brokers, loan originators, stockbrokers, real estate agents, and company insiders (managers). There are also circumstances in which the buyer usually has better information than the seller, such as estate sales as specified in a last will and testament, sales of old art pieces without prior professional valuation, and purchases of health insurance by consumers (or clients) with various risk levels. Asymmetric information can result in one party being defrauded by the other. Because information is easy to create and spread, but difficult to control and trust, it complicates many standard economic theories.

In finance, signaling theory has been applied to the problem of asymmetry of information between a firm’s insiders (managers) and outsiders (stockholders, stakeholders, bondholders, and investors). This theory mainly concerns two aspects of a firm's strategic decisions: capital structure and dividend policy decisions. Stephen Ross (1977), the first to apply signaling theory to finance, argues that the market values a firm's perceived returns, not its actual returns. Managers, as insiders, have monopolistic access to pertinent information about a firm's prospects and expected cash flows. Therefore, when it is in their strategic interest, they can use project financing or dividend policy to send signals to investors about their firm's future. For instance, increased financial leveraging can be used by managers to signal optimistic future prospects. Hayne Leland and David Pyle (1977) assume that owners (entrepreneurs) have better information about the expected value of their firms’ future investment projects than outsiders have. If a firm increases its dividend payout, this is perceived as a positive signal about expected future cash inflows. The market interprets this increase as a sign that the firm will be able to generate enough cash inflows to cover all its debt payments and its dividend payments without increasing the probability of bankruptcy (see Fama, Fisher, Jensen, and Roll 1969; Asquith and Mullins 1983; Richardson, Sefcik, and Thompson 1986).

SIKHISM

Sikhism, a religion that emerged in the Punjab region of India in the fifteenth century, can be said to be the cultural product of the collision between Hinduism and Islam. As such, it combines elements of Islam, such as monotheism and iconoclasm, with certain features of Hinduism, such as the doctrines of reincarnation, karma, and nirvana. While Sikhism is often regarded as a syncretic religion, this interpretation is offensive to Sikhs, who regard their religion as a direct and separate revelation. Crucial to the distinctive character of Sikhism, however, was the rejection of the caste system and its associated rituals and legal apparatus by the Sikh Gurus, or teachers.

Sikhism was founded by Guru Sri Guru Nanak Dev Ji (1469–1539), who was born at Talwandi, a village that is now known as Nankana Sahib, near Lahore in Pakistan. Leaving home to gain religious knowledge, Nanak is said to have encountered Kabir (1440–1518), a saintly figure who was revered by the followers of many religious traditions. Nanak promoted religious tolerance and the equality of women. His most famous saying was: “There is no Hindu, there is no Muslim.” Nanak undertook four extensive journeys around and beyond India, spreading his teaching in Bengal and Assam, in Shri Lanka via Tamil Nadu, in the north toward Kashmir, Ladakh, and Tibet, and finally toward Baghdad and Mecca.
As a system of religious philosophy, Sikhism was traditionally known as the Gurmat (the teachings of the gurus) or Sikh dharma. There were ten Gurus who led the community from the time of Nanaka until 1708. These Gurus came from the Khatri jati, a mercantile caste. The term Sikhism comes from the Sanskrit root sirya, signifying a "disciple" or "student." Sikhs, who now number over twenty-three million adherents around the world, are predominantly inhabitants of the Punjab, where they represent 65 percent of the population. In practical terms, Sikhs are distinguished by the custom in which baptized Sikhs wear the panj kakke (the Five Ks): uncut hair, a small comb, a metal bracelet, a short sword, and a special undergarment. Sikhs served in the British army between 1870 and 1947, and many of them settled outside the Punjab after they were discharged. Thus, there is now a large Sikh diaspora.

Nanak emphasized personal devotion to and intimate faith in God. The principal belief is faith in Vahiguru, or God, who is conceived without gender as a single, personal, and transcendent creator God. Vahiguru is omnipresent and can be comprehended by the "heart" of the true disciple, who achieves religious enlightenment through meditation. The chief obstacles to knowledge and salvation are human attachment to worldly pursuits and interests that determine human involvement in the endless cycle of birth and death, or samsara. This collection of beliefs about sin, responsibility, rebirth and release can be referred to as the dharma-karma-samsara system that Sikhism shares with other religions of the Indian subcontinent. The pursuit of material interests is an illusion, or maya, which is evident in the Five Evils of egoism, anger, greed, attachment, and lust. These evils can only be avoided by intense meditation and verbal repetition of the name of God. In terms of its social teaching, in addition to rejecting caste, Nanak taught that Sikhs should respect the rights of all creatures, especially of human beings. Sikh teaching also underlines egalitarianism, charity, and the sharing of resources.

There are two sources of scriptural authority in Sikhism: the Guru Granth Sahib and the Dasam Granth. The Guru Granth Singh may be referred to as the Adi Granth, or the First Volume. The Adi Granth is the scriptural version created by Arjun Dev in 1604, while the Guru Granth Sahib is the final version produced by Gobind Singh. These teachings take the form of hymns arranged into thirty-one ragas (musical forms) in which they were originally composed. These hymns were originally written in many different languages, and there are both Sanskrit and Arabic portions. The Granth is regarded as the living embodiment of the eleven teachers, and great respect is required in reading them, such as covering the head with a turban or piece of cloth.

Under the guruship of Nanaka, Sikhism was an informal collection of followers, but it eventually came to have a political identity. Guru Ram Das (1534–1581) created the city of Ramaspur, subsequently known as Amritsar. Guru Arjun Dev (1563–1606) built the Golden Temple (Harimandir Sahib), which was completed in 1601, and prepared the sacred text of the Adi Granth. As a result of conflicts with the Mughal authorities, the Sikhs founded the Khalsa (brotherhood and sisterhood of followers who join the community at puberty by undertaking certain rituals) in 1699 to provide for the defense of the community or Panth. As the Sikh community developed a military and political organization, Sikhism became a considerable force in medieval India.

With the death of Banda (Guru Tegh) Bahadur (1621–1675), the ninth Guru of the Sikh faith, the misls, a confederation of Sikh warrior bands, was formed. Toward the end of the Mughal Empire (1526–1858), a Sikh kingdom arose under Maharaja Ranjit Singh, with a capital in Lahore and outer boundaries from the Khyber Pass to China. Eventually, this kingdom (1799–1849) came under British control after the Anglo-Sikh Wars (1845–1846 and 1848–1849).

The partition of India occurred in 1947, and the Sikhs suffered greatly from the resulting violence. Millions were forced to leave their ancestral homeland in the West Punjab. Although the Sikhs eventually prospered, there has been a movement (Damdami Taksal), led by Jarnail Singh Bhindranwale (1947–1984), to create an independent state of Khalistan. This movement led to clashes with the government and communal violence. Bhindranwale was killed in June 1984 in the Golden Temple during a clash with the Indian army. In retaliation, Prime Minister Indira Gandhi was assassinated by her Sikh bodyguard in October 1984.

The attempt to remove Bhindranwale was known as Operation Blue Star in the Indian army, but for Sikhs it represented a desecration of the sacred Golden Temple and the Sikh community. As a result of the military attack, Bhindranwale acquired the status of a martyr, and following Indira Gandhi's assassination there was further communal killing of Sikhs. The consequence of these conflicts was to reinforce the sense of Sikh identity, but also to stimulate the exodus of Sikhs to Europe, North America and East Africa, thereby augmenting the already large Sikh diaspora.

SILICON VALLEY

Silicon Valley, California, USA, is widely hailed as the driving force behind the new high-tech economy. This region has a long history of economic and social struggle that predates and sets the stage for the contemporary terrain of sleek high-technology firms with billionaire chief executive officers (CEOs). Santa Clara Valley (as the region is also known) has been the site of continuous struggles between Native Americans and newcomers, wealthy business owners and low-income workers, and Anglos and people of color and immigrants. This includes the time of the Spanish conquest (beginning in 1769), the gold-rush period (during the mid-1800s), the agricultural period (during the late 1800s through the mid-1900s [Zavella 1987]), and the present-day electronics or high-technology era. During each of these periods, the Santa Clara Valley has been the site of battles over economic and political power that resulted in the relegation of indigenous peoples, immigrants, and people of color to the lowest positions in the social hierarchy. Each period of struggle also saw enormous harm visited upon the natural environment as corporations extracted raw materials for production and sale in global consumer markets (Park and Pellow 2002).

International Business Machines (IBM) built its first West-Coast plant, its Pacific headquarters, in San Jose, California, in 1943. Soon companies such as FMC, Lockheed, General Electric, Sylvania, Fairchild, Memorex, National Semiconductor, and dozens of others located to the area and built what eventually became known as Silicon Valley, producing industrial and consumer electronics that constituted the high-tech revolution.

While a number of industrialists became extraordinarily wealthy as a result of the electronics boom, social inequality was a continuous hallmark of economic development in the region. By 1995, although there was great racial diversity in Santa Clara County (as the total Latino population constituted 23 percent of the county’s residents, Asian Pacific Islanders were 20 percent, and the white population less than 53 percent), Silicon Valley was experiencing ever-increasing wage inequality by race, class, and gender at rates much greater than in the United States as a whole. In 1970 women and people of color constituted an exceedingly small fraction of professional and managerial positions in the valley while these same groups were concentrated in the lower-paid, higher-risk occupations of craft worker, operative, and laborer. As of the early twenty-first century, these patterns remained virtually unchanged, except for class bifurcation among Asian populations as many skilled Chinese and South Asian immigrants moved into higher-paid positions while the Vietnamese population remained concentrated in the lowest-paid positions. Thus, race, class, and gender each operated in ways that generally disadvantaged people of color and women in Silicon Valley.

Despite these social inequalities, Silicon Valley promoters were always able to boast about the environmentally safe image of the high-technology industry and how this sector was distinct from other manufacturing industries because it was “pollution free.” The pollution-free image was shattered in December 1981 when it was discovered that the well that supplied drinking water to homes in south San Jose was contaminated with thousands of gallons of the deadly chemical trichloroethylene (TCA), a solvent used to remove grease from microchips and printed circuit boards after they are manufactured. The toxic waste materials had been leaking from an underground storage tank for at least a year and a half. The responsible party was the Fairchild Semiconductor Corporation, a major firm in the valley.

Most persons working to produce computers and semiconductor chips inside Silicon Valley’s electronics firms are women, immigrants, and people of color. Much of the ethnic and gender segregation in the industry is the result of conscious and selective recruiting on the part of managers (Hossfeld 1990). Compounding the exposure of these workers to the pollution in their neighborhoods is the fact that they hold jobs that are more toxic than those found in any other basic industry. Up to 1,000 different chemicals and metals are used in the various processes required to produce semiconductor chips around the world. Toxic spills that have enraged communities located near chip plants have also impacted the health of workers inside the plants.

Outsourcing of jobs overseas has been a major concern among Silicon Valley workers since the 1980s. Despite earlier no lay-off pledge declarations by high-technology industry leaders, this sector is not fundamentally different from any other with regard to the impact of globalization. The electronics industry is a global industry with investors, owners, factories, workers, and consumer markets the world over. Firms have worked to continuously minimize costs and maximize profits, and this often means importing workers through the H1B visa program (the program that allows foreign workers to come to the
United States to work for one company for a set period of time before they return home, which some critics have labeled a modern form of indentured servitude) or moving factories overseas to find cheap labor in other countries. Electronics firms have moved from the United States to Mexico and then to China, for example, in an effort to hold down costs and boost earnings. Predictably, these practices are accompanied by low-wage, hazardous working conditions and often result in serious occupational health hazards and environmental harm. If Silicon Valley (and those communities around the globe that host a high density of electronics firms) is to have a hopeful future, it will have to be transformed and characterized by social equity and ecologically sustainable economic practices.

SILK ROAD

The term Silk Road (die Seidenstrasse) was first coined by the nineteenth-century German explorer Baron Ferdinand von Richthofen (1833–1905). It broadly describes the ancient trading routes stretching across the Eurasian continent from China to Europe. While silk was clearly one of the earliest and most important commodities traded along the route, precious metals and stones, spices, porcelain, and textiles also traveled the road. More significantly, the Silk Road was an avenue for the exchange of ideas. The technologies of silk production, paper making, gunpowder manufacture, and block printing made their way west across Asia via this highway. Buddhism, Islam, and Christianity entered China via the Silk Road. Migrants, merchants, explorers, pilgrims, refugees, and soldiers brought along with them religious and cultural ideas, products, flora and fauna, and plagues and disease in this gigantic cross-continental exchange.

Thus, the Silk Road is a symbol of the globalization of trade, technology, and ideology for the premodern world.

Although Chinese silk was found in Europe as early as 500 BCE, well recorded trading started only when China gained control of its western frontier during the Western Han dynasty (202 BCE –9 CE). The first route started from China’s capital at the time, Chang-An (now Xian), and continued through the northwest frontier of China and the elaborate trading networks of major Eurasian civilization zones in Central Asia, Persia, and Roman Europe. Traffic along the Silk Road was disrupted at times of political disintegration, such as the collapse of the Han dynasty around 220 CE. A second, “southern” Silk Road started in southwest China, passing through China’s Sichuan and Yunnan provinces and Burma to reach India. Trade in silk between China and India increased substantially between the fourth and sixth centuries when the northern route became unstable.

During the first two hundred years of the Tang dynasty (618–907 CE) silk trade via the northern route thrived again, only to decline toward the end of dynasty when Tang lost control of the northwestern territories to the Arabs. The route was significantly revived under the Mongol Empire established by Genghis Khan (1167–1227). Safe trade routes, effective post stations, the use of paper money, and the elimination of trade barriers marked the high stage of East-West exchange, which saw the famous travels of Marco Polo.

As shipbuilding technology progressed, maritime routes became easier and safer; this was the most important contributing factor to the relative decline of the overland Silk Road from around the fourteenth century. A significant breakthrough came in 1488 when Portuguese ships found their way to East Asia by bypassing the mighty Ottoman barrier and rounding the Cape of Good Hope. Meanwhile, in China the centers of economic and cultural activities began to shift decisively southward, with the lower Yangzi delta area (roughly in the Jiangsu and Zhejiang provinces) emerging as the most important center of production of luxury goods, including silk. This development helped accelerate the geographic shift in Eurasian trade from the overland to the sea route, which is sometimes called the maritime Silk Road.

Accompanying the trade in silk was the slow but cumulative diffusion of the craft of silk-making, which traveled from China through Central Asia, Persia, Anatolia, North Africa, and Eastern and Southern Europe, and finally, in the seventeenth and eighteenth centuries, took hold in the newly discovered American continent.

SILVER INDUSTRY

The world silver industry consists of miners, refiners, traders, and fabricators. Generally speaking, the silver industry overall grew in the decade from 1996 to 2005, with mine supply increasing to meet rising fabrication demand and refiners and traders handling greater volumes to facilitate this growth.

While silver prices were generally flat through most of this decade, prices began rising out of the US$4 to US$5 per ounce range where they had been trapped in 2003. During 2005 and the first half of 2006, silver prices rose sharply, reaching a decade-long high of more than US$9 per ounce in late 2005 and soaring further to nearly US$15 per ounce by April 2006. While low prices hurt the mining sector through much of the 1990s and early 2000s, they had a long-run effect of spurring fabrication demand, particularly nontraditional uses of silver in diverse areas from electronics to medicine.

According to a 2006 report by Peter Klapwijk, world mine production of silver was generally on the increase between 1996 and 2005, during which time production rose from just under 500 million ounces to approximately 642 million ounces. William E. Brooks reported in 2006 that approximately two-thirds of mined silver worldwide is produced as a by-product of copper, lead, zinc, and gold production. As a consequence, silver is mined and enters the market regardless of the price.

Silver resources are spread over all continents (excluding Antarctica and Greenland, where resource estimates are unavailable). The largest producing country in 2005 was Peru, which accounted for slightly more that 15 percent of world output. Peru was followed by Mexico, Australia, China, Chile, Russia, Poland, and the United States. Estimated minable world silver reserves—that is, silver contained in ore that can be mined at a profit—amount to approximately 8.7 billion ounces (Brooks 2006). It is not known, however, how many of these ounces could be recoverable through primary rather than by-product production.

LABOR CONDITIONS AND ENVIRONMENTAL ISSUES

Labor conditions and the degree of unionization in the silver mining industry vary widely around the world. In the United States, for example, every mine worker undergoes safety training before being employed and takes a periodic refresher course. Silver mining, and hard-rock mining in general, however, is significantly safer than coal mining. Coal mining involves digging into a combustible material, which is the cause of many coal mine accidents. This is not the case with hard-rock mining.

Because silver mines tend to be fairly large-scale operations employing several hundred workers at a moderate size mine, the workforce is amenable to unionization. The degree of unionization, however, varies widely depending on national and state or provincial laws. In the western United States, where most of U.S. output comes from, mine workers tend not to be unionized, but many of the specialized tradespeople, such as electrical workers, pipe fitters, and some construction workers, do tend to be unionized. In general, whether union members or not, mine workers are typically among the highest paid industrial workers.

Environmental reclamation laws also vary widely around the world. In the United States environmental laws concerning discharge of pollutants and reclamation are generally administered by state agencies in compliance with U.S. Environmental Protection Agency regulations. In other countries similar regulations may or may not be in force. Nevertheless, international banking concerns typically make compliance with U.S. environmental standards a general condition of financing mine development in other countries. These conditions are generally imposed by lenders to prevent environmental degradation being used as a rationale for nationalization and confiscation of a mining property. Not all mines, however, are financed through international lenders, and in these cases compliance is less certain although there is still an incentive for operators to avoid confiscation and nationalization.

REPROCESSING, REFINING, AND COMMODITY EXCHANGES

In addition to mining, silver also makes its way into the world supply chain from the reprocessing of scrap metal that comes from various fabrication processes and via sales from government stockpiles. In 2005 mined silver accounted for approximately 70 percent of the total supply, while scrap accounted for 21 percent. Historically, reprocessing photographic wastes has been the major

BIBLIOGRAPHY

Debin Ma
source of scrap, but this is changing because of a variety of factors. Other major sources of scrap include jewelry and silverware manufacturing. In addition to reprocessing scrap, government sales account for 7 percent of the silver supply and producer hedging for 2 percent (Klapwijk 2006). All of these sources combined for a total supply of 911.9 million ounces in 2005 (Klapwijk 2006).

In the case of mined silver, producers ship unrefined product to a refinery for reduction to a commercial grade product. There are many refineries around the world that can process unrefined product, with more than twenty of them located in the United States. These refineries also melt down and refine other types of scrap material to produce a commercial grade product. These commercial grade products can range from products that are alloyed with other metals for special purposes and sold under contract to jewelers and other fabricators to silver bullion that is 99.99 percent pure silver.

Many major commodity exchanges around the world make a market in bullion silver. These include markets in London, New York, and Tokyo, but perhaps the largest is the London Bullion Market Association. Traders in these markets sell silver in “spot” markets, that is, for immediate delivery, and deal in futures and options contracts for delivery in the future.

PRODUCTS
As noted, fabrication demand has increased since the mid-1990s. The more interesting story behind this increase, however, has been the change in the mix of products fabricated. Historically, the major uses of silver were the minting of coins and the fabrication of jewelry, silverware, and objects of art such as candlesticks and bowls. During the twentieth century photographic processing emerged as a major use of silver, and from the middle of the twentieth century the use of silver for coinage diminished, though substantially only in the United States. Fabrication demand for photography has started to decline as consumers shift from film-based photography to digital cameras. At the same time, however, in spite of the decline in the traditional uses of silver in coinage and photography, demand for silver has been growing as new uses have been found for this metal based on its particular qualities, such as its being an excellent electronic conductor and having high degrees of malleability and reflectivity.

Silver is commonly used in a variety of batteries, from most quartz watch batteries to batteries used in the aerospace industry. Silver batteries are lighter weight and can deliver more power per weight than traditional lead-acid batteries.

Because silver alloys or combines with other metals well, it is commonly used as a coating for bearings in jet engines and for brazing and soldering in electronics and other manufacturing. Perhaps one of the most common uses of silver as a coating is in the manufacture of mirrors. Silver is also used in windows that reflect solar radiation and heat and in eyeglasses. In addition the metal is also an important catalyst used in manufacturing a variety of plastics and chemicals.

The use of silver in the electronics industry is also growing. Because of its conductivity and resiliency, silver contacts are widely used in many industries. High-voltage contacts at power plants and in manufacturing plants frequently are made of silver or are silver coated. Automobiles have silver contacts in ignition systems, other electronic systems, and safety systems, such as air bags. Silver is also widely used for contacts and circuitry in computers, including the contacts under computer keyboard keys.

In medicine silver has long been used as a biocide. Since before 500 BCE it has been known that water, milk, vinegar, and other foods resist spoilage better when stored in silver vessels than in other containers. This characteristic of silver has led to its use in water purification systems, bandages, and other antibacterial, antifungal, and antiviral applications.

SIMILARITY/ATTRACTION THEORY
Similarity/attraction theory posits that people like and are attracted to others who are similar, rather than dissimilar, to themselves; “birds of a feather,” the adage goes, “flock together.” Social scientific research has provided considerable support for tenets of the theory since the mid-1900s. Researchers from a variety of fields such as marketing, political science, social psychology, and sociology have contributed to and gleaned information from empirical tests of similarity/attraction theory. The theory provides a parsimonious explanatory and predictive framework for examining how and why people are attracted to and influenced by others in their social worlds.

A large body of research investigates the role that similarity of attitudes plays in attraction. According to stud-
ies by Ellen Berscheid and Elaine H. Walster (1969) and Donn Byrne (1971) in general people are most attracted to others who share similar attitudes. Additionally people who share similar important attitudes (e.g., attitudes concerning home and family) are more likely to be attracted to each other than those who share less important attitudes (e.g., attitudes toward certain fabric softeners).

There are several reasons why people prefer the company of others who espouse attributes, especially important attitudes, which are similar to their own (Berscheid and Walster 1969; Byrne 1971). Most importantly perhaps, sharing similar attitudes provides corroboration that a person is not alone in his or her belief; they might even be correct to hold the attitudes in question. Other possible reasons suggested for why people prefer others who are similar to themselves are that (1) knowledge of similar attitudes may help people to predict others’ future behaviors, providing a predictive “window” into the other’s behavioral predictions, and (2) people may be more likely to assume that others who hold similar attitudes to themselves have a greater chance of being attracted to them, a “likeness begets liking” explanation.

In addition to people’s inclinations to be attracted to those who share similar attitudes, people are also attracted to others who manifest personality characteristics (e.g., optimism, self-esteem, shyness, conscientiousness) that are similar to their own. In fact people may choose to associate with certain others because they have similar personalities. For example friends are more likely to share personality traits than nonfriends. Moreover, marital partners share more similar personalities than people in randomly assigned pairs. Indeed personality similarity may play a key role in marital happiness and longevity (Berscheid and Walster 1969; Byrne 1971).

Furthermore people are attracted to romantic partners who share similar physical characteristics and levels of physical attractiveness. Tall people are more likely to marry tall partners than short ones, and attractive people are more likely to marry attractive partners than unattractive ones.

People’s preference for similarity in social partners is not limited to the aforementioned domains, though. Research has demonstrated that people report greater liking for and attraction to people who are like them in the following areas as well: socioeconomic status, religious beliefs, social habits (e.g., frequency of attending parties), bad habits (e.g., drinking and smoking), ethnicity, and intelligence.

Similarity/attraction theory may not hold in all social instances, however. For example some scholars have suggested that people may be more likely to be attracted to partners who complement rather than replicate certain attributes. This complementarity view of attraction explains, for example, why attractive younger women may form successful marital unions with much older, wealthier men. Along similar lines people may not like others who share negative personality traits with them. Rather than be constantly reminded of their faults in a given dimension through the presence of someone similar, people may prefer to interact with others who they believe will “bring out the best” in them.

Additionally some researchers, such as Milton Rosenbaum in a 1986 study, have suggested that attitudinal dissimilarity, rather than attitudinal similarity, drives the similarity-liking link. According to the dissimilarity-repulsion view people’s motivation to avoid social interactions with dissimilar others is stronger than, or at least as strong as, people’s desire to affiliate with like-minded others. Indeed a 2000 study by Ramadhari Singh and Soo Yan Ho revealed that, under certain circumstances, the influence of attitudinal similarity and dissimilarity may exert equivalent and opposite effects on liking. Further in some cases, dissimilar attitudes may have a stronger influence on interpersonal attraction than similar attitudes (Singh and Ho 2000).

In summary similarity-attraction theory attempts to explain and predict interpersonal liking by asserting that people are attracted to others who are similar to themselves. Consistent with this view, research has revealed that people prefer to affiliate with those who share similar attitudes, personalities, physical attributes, and a host of other characteristics compared to others who do not. Though similarity/attraction theory explains many cases of interpersonal attraction, it may not accurately predict all attraction outcomes. In some cases complementarity or avoidance of dissimilar others may better explain certain patterns of human liking.

SIMON, HERBERT A.
1916–2001

Born on June 15, 1916, in Milwaukee, Wisconsin, Simon was the second son of Arthur Simon, an immigrant German who was an electrical engineer and inventor, and Edna Merkel Simon, a third-generation American who was an accomplished pianist. Determined to become a mathematical social scientist, he bid farewell to Milwaukee at age seventeen to enter the hall of academe in Chicago, where he obtained his BA in 1936 and his graduate degree in 1943, both in political science. During his professional career, he was affiliated with the University of California at Berkeley, the Illinois Institute of Technology, the Cowles Commission, the Rand Corporation, and Carnegie-Mellon University, which was still known as the Carnegie Institute of Technology when Simon moved there in 1949. At the time of his death, he was the Richard King Mellon Professor of Computer Science and Psychology at Carnegie.

Starting off in political science and then moving through several disciplinary domains such as management theory, economics, cognitive psychology, and artificial intelligence, Simon’s entire academic career was focused on understanding human decision-making and problem-solving processes and their implications for social institutions. In economics, Simon has become mostly known for his psychology-inspired criticism of the rationality postulate. In particular, he criticized the four basic assumptions of neoclassical economics: (1) the presupposition that each economic agent had a well-defined utility or profit function; (2) the idea that all alternative strategies were presumed to be known; (3) the assumption that all the consequences that follow upon each of these strategies could be determined with certainty; and (4) the presumption that the comparative evaluation of these sets of consequences was driven by a universal desire to maximize expected utility or expected profit. For Simon, these four assumptions clashed with insights from psychology that there were external, social constraints and internal, cognitive limitations to decision-making, upon which he based the opposing assumptions of his bounded rationality program.

Simon argued that, first, the bounded rationality program assumed that decision-makers were confronted by the need to optimize several, sometimes competing, goals. Second, Simon’s bounded rationality program postulated a process for generating alternatives. Third, Simon argued that individuals mostly applied approximate solutions to problems. Finally, Simon’s bounded rationality theory proposed a satisficing strategy. It sought to identify, in theory and in actual behavior, procedures for choosing that were computationally simpler and argued that individuals picked the first choice that met a preset acceptance criterion. Simon also became known for contributions such as the so-called Hawkins-Simon conditions for stability, his findings on certainty equivalence, his research on size distributions of firms and organizations, and his insights on causality, identifiability, and aggregation.

In 1978, Simon received the Nobel Prize in economics for what the Nobel committee called “his pioneering research into the decision-making process within economic organizations.” Bounded rationality has received renewed attention in recent years from, among others, behavioral economists, game theorists, and rational expectations economists. Yet, whereas Simon saw bounded rationality as an alternative to mainstream economics, many contemporary theorists attempt to use his ideas to solve some of the problems in their neoclassical program.

SIMULTANEOUS EQUATION BIAS

Simultaneous equation bias is a fundamental problem in many applications of regression analysis in the social sci-
ences that arises when a right-hand side, \( X \), variable is not truly exogenous (i.e., it is a function of other variables). In general, ordinary least squares (OLS) regression applied to a single equation from a system of simultaneous equations will produce biased, that is, systematically wrong, parameter estimates. Furthermore, the bias from OLS does not decrease as the sample size increases. Estimating parameters from a simultaneous equation model requires advanced methods, of which the most popular today is two-stage least squares (2SLS).

### UNDERSTANDING OLS AND BIAS

Consider the following single-equation regression model:

\[
y_i = \beta_0 + \beta_1 x_i + \epsilon_i.
\]

This data generation process (DGP) says that each value (denoted by the subscript) of the dependent variable, \( y \), is produced by taking \( \beta_0 \) and adding \( \beta_1 \) times the value of the independent variable, \( x \), and adding a draw from the random error distribution, \( \epsilon_i \).

To estimate the value of the slope parameter, \( \beta_1 \), from a sample of \( x \), \( y \) observations, we fit a line using ordinary least squares, so named because coefficients are chosen to minimize the sum of squared residuals. A residual is the vertical distance between the actual and predicted value. The equation of the fitted line is

\[
\text{Predicted } y = b_0 + b_1 x.
\]

The slope coefficient from the OLS fitted line, \( b_1 \), is our estimate of the unknown parameter \( \beta_1 \). Because we are dealing with a finite sample, we know that our estimate, \( b_1 \), is probably not exactly equal to the parameter value, \( \beta_1 \). If we generated another sample, we would get another value of \( b_1 \) for that sample. This shows that the slope coefficient from the OLS fitted line is actually a random variable.

Figure 1 provides a concrete example of the abstract ideas underlying OLS. The points in the graph correspond to those in the table. The estimated slope, 4.2, does not equal the true slope, 5, because of the random error term, which in this case is normally distributed with mean zero and standard deviation of 50. A new sample of ten observations would have the same \( X \) values, but the \( Y \)'s would be different and, thus, the estimated slope from the fitted line would change.

There are other estimators (recipes for fitting the line) besides OLS. The circle in Figure 2 represents all of the possible estimators. The vertical oval contains all of the linear estimators. This does not refer to the fitted line itself, which can have a curved or other nonlinear shape, but to the algorithm for computing the estimator. All of the unbiased estimators are included in the horizontal oval. **Unbiasedness** is a desirable property referring to the accuracy of an estimator. Unbiased estimators produce estimates that are, on average, equal to the parameter value. **Bias** means that the estimator is systematically wrong, that is, its expected value does not equal the parameter value. The area where the ovals overlap in Figure 2 is that subset of estimators, including OLS, which are both linear and unbiased.

According to the Gauss-Markov Theorem, when the DGP obeys certain conditions, OLS is the best, linear, unbiased estimator (BLUE). Of all of the linear and unbiased estimators, OLS is the best because it has the small-
est variance. In other words, there are other estimators that are linear and unbiased (centered on \( \beta_1 \)), but they have greater variability than OLS. The goal is unbiased estimators with the highest precision, and the Gauss-Markov Theorem guarantees that OLS fits the bill.

Figure 3 shows histograms for three rival linear estimators for a DGP that conforms to the Gauss-Markov conditions. The histograms reflect the estimates produced by each estimator. Rival 1 is biased. It produces estimates that are systematically too low. Rival 2 and OLS are unbiased because each one is centered on the true parameter value. Although both are accurate, OLS is more precise. In other words, using OLS rather than Rival 2 is more likely to give estimates near the true parameter value. The Gauss-Markov Theorem says that OLS is the most precise estimator in the class of linear, unbiased estimators.

SIMULTANEOUS EQUATION BIAS

Suppose one faces a simultaneous equation DGP like this:

\[
\begin{align*}
y_1 &= \beta_0 + \beta_1 x + \beta_2 y_2 + \epsilon_1 \\
y_2 &= \alpha_0 + \alpha_1 y_1 + \epsilon_2.
\end{align*}
\]

There are two dependent (or endogenous) variables, \( y_1 \) and \( y_2 \). Each equation has a regressor (a right-hand side variable) that is a dependent variable.

If one is interested in the effect of \( y_1 \) on \( y_2 \), can one toss out the first equation and treat the second equation as a single-equation model? In other words, what happens if one ignores the simultaneity and simply runs an OLS regression on an individual equation? One gets simultaneous equation bias. The OLS estimator of \( \beta_1 \), the slope parameter in the second equation, will be biased, that is, it will not be centered on \( \beta_1 \). With every sample to which one applies the OLS recipe, the resulting estimates will be systematically wrong. OLS is now behaving like the Rival 1 estimator in Figure 3 (although one does not know if the bias centers OLS above or below the true parameter value).

Consider the following concrete example. A researcher is interested in estimating the effect of the crime rate (number of crimes per 100,000 people per year) on enforcement spending (dollars per person per year). As the crime rate rises, more police officers and prison guards are needed, so enforcement spending will rise. The researcher is interested in estimating the slope coefficient, \( \beta_1 \), in the following model:

\[
\text{Enforcement Spending} = \beta_0 + \beta_1 \text{CrimeRate} + \epsilon.
\]

Unfortunately, in this situation, as in most social science applications, the real world does not follow a single-equation DGP. Although it is true that government policy makers allocate resources to enforcement spending depending on the crime rate, criminals make decisions based on enforcement spending (and other variables). Increased crime causes more enforcement spending, but more enforcement spending causes less crime. This kind of feedback loop is common in the social sciences. The appropriate model is not a single-equation DGP because the crime rate is not a truly exogenous variable. Instead, the researcher must cope with a simultaneous system of equations where both enforcement spending and crime rate are dependent variables.

If the researcher naively applies OLS to the single equation, her estimate of the effect of crime on enforcement spending, \( \beta_1 \), will be biased. Because ignoring the fact that the crime rate is actually a dependent variable with its own DGP equation causes this bias, it is called simultaneous equation (or simultaneity) bias.

The source of the poor performance of the OLS estimator lies in the fact that we have a violation of the conditions required for the Gauss-Markov Theorem: The crime rate is a right-hand side variable that is not independent of the error term. In a given year a high crime rate will result in high enforcement spending, but that will trigger a low crime rate. Conversely, a low enforcement spending year will lead to more crime. When the error term is correlated with a regressor, OLS breaks down and is no longer an unbiased estimator.

AVOIDING SIMULTANEOUS EQUATION BIAS

Estimating an equation with dependent variables on the right-hand side requires advanced methods. It is important to recognize that increasing the sample size or adding explanatory variables to the single-equation regression will not solve the problem.
The approach typically taken is called two-stage least squares (2SLS). In the first stage, an OLS regression utilizes truly exogenous variables (called instrumental variables) to create artificial variables. In the second stage, these artificial variables are then used in place of the endogenous, right-hand side variables in each equation in the system.

In the enforcement spending and crime rate example, the researcher would first regress the crime rate on a set of truly exogenous variables to create a Predicted Crime Rate variable. Determining the instruments to be used in the first stage regression is a crucial step in the 2SLS procedure. In the second stage, she would substitute the Predicted Crime Rate for the Crime Rate variable and run OLS. It can be shown that as the sample size increases, the expected value of the 2SLS estimator gets closer to the true parameter value. Thus, unlike OLS, 2SLS is a consistent estimator of a parameter in a simultaneous equation model.

In practice, two separate regressions are not actually run. Modern statistical software packages have an option for 2SLS that performs the calculations, computing appropriate standard errors and other regression statistics, in one step. As a practical matter, even if there are strong theoretical reasons to suspect the presence of simultaneous equation bias, it need not be a particularly large bias.

A BRIEF HISTORY OF SIMULTANEOUS EQUATION BIAS

Attempts to estimate demand curves in the first quarter of the twentieth century led economists to model supply and demand equations as a simultaneous system. This work culminated in the probabilistic revolution in the 1940s. In “The Probability Approach in Econometrics,” Trygve Haavelmo called for explicit description of the data generation process, including the source of variation in the error term and the use of a simultaneous system of equations to model complicated interrelationships among variables.

Haavelmo’s program was supported by Tjalling Koopmans and others at the Cowles Commission, a research think tank housed at the University of Chicago from 1939 to 1955. These econometricians made progress in several key areas, including the identification problem, understanding the nature of simultaneous equation bias, and methods for properly estimating an equation embedded in a simultaneous system. They concentrated their simultaneous equation estimation efforts on full- and limited-information maximum likelihood. Two-stage least squares, a much more efficient computational approach, was not discovered—independently by Henri Theil and Robert Basmann—until the 1950s.

SUMMARY

Simultaneous equation bias occurs when an ordinary least squares regression is used to estimate an individual equation that is actually part of a simultaneous system of equations. It is extremely common in social science applications because almost all variables are determined by complex interactions with each other. The bias lies in the estimated coefficients, which are not centered on their true parameter values. Advanced methods, designed to eliminate simultaneous equation bias, use instrumental variables in the first stage of a two-stage least squares procedure.

SEE Linear Systems; Nonlinear Systems.

SIN

Sin, in most religions, may be rooted in human “being” but shows itself in human action. This action is of a negative character and represents what the Catholic theologian Karl Rahner (1904–1984) described as an awareness...
that “things are not the way they ought to be” (Rahner 1961–1979, p. 164). In some faiths the stress is on the corporate character of sin: what causes it, how it is manifested, and what a community does with it. Thus when ancient Israel offended against the way “things ought to be” as prescribed by Yahweh, the people together experienced punishment by this God and recognized a need to atone for sin, to bring the lives of the community and individuals in it in line with the way “things ought to be.”

The source of that sense of “ought” may relate to the ways humans in the earliest and simplest of circumstances sensed that there must be a right way, but they were not able to attain it or resisted attainment. Or the source may be in conscience. How the separate faiths account for conscience or any other inner apparatus that inspires and informs conduct tells much about what each considers to be sin and what each prescribes to be a remedy, often called atonement. Alongside a primitive sense of “oughtness” and “conscience,” a third way of discerning the source of sin is in divine revelation. Ordinarily this means that gifted and charismatic individuals, prophets within the tradition, judge people against the standard of what some holy book has described as conformity to the proper way or prescribed as atoning action.

In cultures informed by the Bible of the Jews and Christians, the definitions and experiences of sin come to focus in a witness to a living creator God who interacts with people, stipulating how they should live, and who in a sacred scripture sets forth a covenant, a divine-human pact that must be followed if God is to be pleased or given an opportunity to show mercy. Whether on a communal or an individual level and whether on gross or trivial scales, sin is seen as a free violation of what God commands and expects. In Christianity there is a similar stress on locating the errant individual in light of how he or she affirms or departs from a divine-human covenant. Christianity preaches that God is both just and merciful. Being merciful, God can recognize value in the efforts of those who try to live in accord with divine commands and can extend mercy even where there is failure.

Sin in most Christian traditions is seen against the background of what Christians call original sin, which they perceive as a reality even if they have difficulty accounting for it along with other negative features and experiences in a universe created and governed by a good God. Traditionally original sin, the factor in human experience that makes it impossible for anyone to live a perfect life, is traced to Adam and Eve, the first humans, according to the account in Genesis. Tempted by an external agent, “the serpent,” they willingly responded and went against the express decree of God. When, acting upon this evil agency in and around them, their heirs, all humans, engage in actual sin—as also a technical term—they are breaking the covenant. In some biblical language, sin means “missing the mark” or “transgressing God’s boundaries.”

In Judaism and Christianity various paths of return to the covenant and God’s good graces are prescribed and are called atonement or reconciliation to God. The same God who set forth the mark that was missed or the boundary transgressed and who can be wrathful and will exact punishment is also witnessed to as merciful. Through atoning activities, for Christians in the agency of Jesus Christ as God’s Son who is offered up in a loving sacrifice for others, believers are set on a path that allows them to approach hitting the mark, staying in the boundaries, pleasing God, and receiving a reward, thanks to the grace of this covenanting God. One of the main differences between Roman Catholic and Protestant varieties of Christianity is the stress in the former on human participation in redeeming activities through “good works,” while for Protestantism, which also expects good works, the accent is more on God’s grace.

In virtually every faith, though terms like original sin and transgressing may be absent, there is some pattern or ideal to be followed to place human individuals or the community in a positive relation to the highest power or source. This is usually “God,” under a variety of names, such as for Muslims Allah. Allah has created an ordered universe, but humans who violate the laws of Allah cause disorder and are evil or act evi1y. While Islam does not employ concepts such as original sin, Muslims know that they are in a universe where something is expected of them that they do not and cannot achieve on their own. Practicing rites of prayer, almsgiving, and submission to Allah represents a turning from sin and the threat of punishment and makes room for Allah the All-Merciful to show mercy.

Religious communities that either do not witness to God or gods, such as Buddhism, or where deity is represented by various supernatural beings, as in Hinduism, will not speak in terms of a covenant with a merciful God that humans choose to follow or break. Thus in Buddhism, which cannot connect human evil with a covenanting God because there is no witness to God, the concern is to deal with negative forces and actions, summarized in the term karma. Individual actions are measured in the light of whether the intention of an act was positive or negative, with the goal of dealing with suffering, which is a universal human experience, by disciplines and practices that in their intention make room for good and positive karma and actions.

In Hinduism there is also no covenant with the one God (monotheism) or original sin, yet there are also prescribed paths for conduct pleasing to the deities adored in Hinduism. In Hinduism, as well as most other faiths, there are actions equivalent to atoning ones in monothe-
istic faiths, actions that through conduct and proper ritual or meditation lead one to positive conduct and reward. In almost all faiths atoning activities that counter sin or bad karma have positive rewards in this life and, in many faiths, in life after death. This is so in Christian resurrection or Hindu reincarnation. In none of the faiths is the realistic note wholly lost. That is, they do not envision a complete overcoming of evil as expressed in human sin but teach ways to live and think in the face of such evil that resides in the external world and in the self.

**BIBLIOGRAPHY**

**SINGER, HANS**

1910–2006

Hans Wolfgang Singer was born on November 29, 1910, in Elberfeld, Germany, into a Jewish family. When the Nazis rose to power, he fled Germany to study at Cambridge University, where he completed a PhD in economics on a refugee scholarship. After a brief academic career, he joined the United Nations (UN). After his extensive work (1947–1969) with the UN, he joined the newly established Institute for Development Studies (IDS) at the University of Sussex. Until his death on February 26, 2006, he maintained his academic contact with IDS.

Singer was widely acclaimed because of his association with the Prebisch-Singer hypothesis. He got the idea while preparing a UN report in 1949. The report was a follow-up of the League of Nations 1945 report noting that during the sixty years preceding 1938, primary product prices had fallen relative to prices of manufactures. On the basis of the UN report, the Argentine economist in charge of the UN Economic Commission for Latin America (ECLA), Raul Prebisch, and Singer raised the issue of declining terms-of-trade of primary products and the primary-producing less developed countries (LDCs) vis-à-vis manufactures and the manufacture-exporting developed countries (DCs). They questioned the dominant classical policy prescription of free trade and international division of labor according to the Ricardian dictum of comparative advantages.

The Prebisch-Singer hypothesis was virtually discarded in mainstream economics in the face of strong statistical objections against it. Nevertheless, Singer continued to believe it to be a fact, although he did not necessarily know how to go about proving it. In 1986 the economist Prabirjit Sarkar provided a strong statistical support in favor of it. This encouraged Singer to collaborate with Sarkar to work further in this field, which led in 1991 to the Sarkar-Singer extension of the hypothesis in the field of manufacture exports of the LDCs to pay for their manufacture imports from the DCs. This extension provided a further support to the Prebisch-Singer hypothesis, particularly its core that is primarily concerned with the relationships between types of countries (unequal relationships between the LDCs and the DCs)—not just with the relationships between types of commodities (primary products and manufactures). In the process it has become more relevant to the early twenty-first century world with increasing trade of manufactures between the LDCs and the DCs.

Throughout his life Singer maintained a voluminous flow of professional publications on all aspects of development—from long-term trends in prices to short-term commodity price instability, food security, and welfare of children. He advocated food aid, concessional loans for the development and management of the affairs of debt-ridden LDCs.

Singer was a follower of the original scheme of the English economist John Maynard Keynes regarding the then future world economic system tabled at the Bretton Woods Conference (1944) for its consideration. He shared Keynes’s concern for commodity price stability for the sake of stability of the world economy. Like Keynes, he believed that surplus and deficit in balance of payments were two sides of the same coin, and so both sides should bear the burden of adjustment in balance of payments disequilibrium. But the system that came up with the International Monetary Fund (IMF) and the World Bank penalizes the deficit countries in spite of their role in increasing effective demand and thereby promoting world output and employment. He identified this as one major cause of the agony of the LDCs. He was critical of the neoliberal one-size-fit-for-all policy prescriptions of the IMF and World Bank for the debt-ridden LDCs. He anticipated much of the writings of the dissident World Bank economist Joseph Stiglitz on the discontents of globalization.
a coalition with the Bharatiya Janata Party (BJP) on the right and the Communist Party on the left and defeated the Congress Party in the 1989 general elections. After various political struggles among the coalition groups, Singh was asked to take the mantle of prime minister of India. His minority Janata Party government was dependent on support in parliament from the Congress Party and the Communist Party. When the Congress Party withdrew its support, the Singh government fell.

Singh was known for his promotion of just causes, calling for justice for Muslims in Kashmir and Sikhs in Punjab while maintaining the territorial integrity of India. After serving as prime minister for less than a year, he faded from state and national politics, especially when he was diagnosed with cancer, which remained in remission in early 2007.

SITTING BULL
1831–1890

Sitting Bull was most likely born in the winter of 1831 at Many Caches, along the Grand River near present-day Bullhead, South Dakota. Originally named Jumping Badger, he was the son of a Hunkpapa Lakota chief, Tatanka Iyotanka (Sitting Bull), and Her Holy Door. The son would become one of the most famous American Indian leaders in history, a great war chief and spiritual leader who earned lasting fame as the man most responsible for the defeat of Colonel George Armstrong Custer at the Battle of Little Big Horn in 1876.

After counting his first coup at the age of fourteen, Jumping Badger received his father’s name, Sitting Bull. He early established himself as a courageous warrior and a highly skilled hunter. He also earned the status of a wicasa wakan, or holy man, who could interpret visions and dreams from the spirits. He was also known for his generosity and for his devotion to family members. All of these qualities collectively earned him widespread esteem and helped him to rise to the position of perhaps the most revered Indian leader of the Plains.

As the United States government sought to force tribes onto reservations, Sitting Bull increasingly came to represent, for both Indian and Euro-American, resistance to United States expansion into the Plains. However, he adopted a defensive strategy, fighting only when he perceived a clear threat to his people.

That strategy worked reasonably well until 1876 when General Alfred H. Terry led an expedition against Sitting Bull’s camp. Terry’s plan was for Colonel John Gibbon (accompanied by Terry) and the Seventh Cavalry under Custer to converge simultaneously on the camp from different directions.

By late June, seven thousand or more Lakotas and Cheyennes had joined his village, and Sitting Bull’s vision in which he saw soldiers falling upside down into the camp had helped convince his people of their coming victory. In addition, a successful battle against General George Crook’s troops along the Rosebud River in southeastern Montana had further bolstered their confidence.

When Custer arrived at Sitting Bull’s encampment along the Little Big Horn, he chose not to wait for Terry and Gibbon. Instead, he attacked on June 25 after further eroding his chance for victory by dividing his forces. Custer and everyone with him died in what would become perhaps the most famous defeat in U.S. military history and be immortalized as Custer’s Last Stand.

A lingering controversy regarding Sitting Bull’s role in the battle originated with accusations by Gall, a rival of Sitting Bull’s, that the Hunkpapa chief was not present during the battle and played no role in it. Historians now agree that Gall was wrong.

The victory for Sitting Bull was short-lived. Faced with a relentless pursuit by Colonel Nelson Miles, Sitting Bull made his way to Canada, arriving in May 1877. Finally, he surrendered to U.S. officials at Fort Buford in northwestern Dakota Territory on July 20, 1881. He spent most of his remaining years on Standing Rock Reservation, located in central North and South Dakota.

For about four months in 1885, Sitting Bull toured with Buffalo Bill Cody’s Wild West Show. During this time, he befriended the young shooting specialist Annie Oakley.

By 1890, a mystical ceremony known as the Ghost Dance was spreading across reservations. Proponents believed that the dance would reverse time, removing soldiers from the land, bringing the buffalo back, and restoring the Indian way of life.

Questions have lingered regarding Sitting Bull’s attitude toward the Ghost Dance. He seemed to believe that the new religion might possess some truth and had encouraged the dance at Standing Rock while not participating himself. Perhaps to test the validity of the dance, he was planning a trip to Pine Ridge Reservation in southwestern South Dakota, a hotbed of Ghost Dance activism. Officials grew concerned that Sitting Bull might use the movement as a means to stir up resistance, even war, against the government.

To prevent Sitting Bull from leaving, James McLaughlin, the Standing Rock agent, ordered his arrest. Early in the morning of December 15, 1890, a contingent of Lakota police arrived at his cabin. As they attempted to arrest Sitting Bull, supporters came to his defense. Violence soon erupted, and Sitting Bull was shot twice, the second time in the head, and killed. As historians learned more about his life, Sitting Bull gradually emerged during the twentieth century as a great American leader—a complex man who did much more than defeat the Seventh Cavalry at Little Big Horn.

Skill

Skill is usually understood as an ability to do something well, either manually, mentally, or both. In contrast to terms that denote only potential for acquiring some ability (such as natural ability, talent, aptitude, or capacity), the term skill usually means actual competence that has been acquired by training, schooling, or practice. The concept is used in several disciplines (most importantly economics, sociology, psychology, education, and ergonomics), has many meanings, and is applied for different purposes and in a variety of contexts.

The term skill is used mainly to refer to (1) a level of individual performance, in the sense of accuracy and speed in performing particular tasks, or (2) qualities required for successful performance in particular jobs and tasks. Economists and educational psychologists tend to use the concept of skill in the first sense: to describe the abilities acquired by an individual such as a worker, which may include cognitive skills, manual dexterity, knowledge, and social skills. These researchers often take skill as an independent variable and use it, for example, in predicting wage levels. In sociology, on the contrary, skills are often taken as qualities required of a particular job, in terms of the range and complexity of the tasks involved, level of discretion over work and time, and the knowledge and training needed to learn the job. Many sociologists thus view skill as a dependent variable and try to explain variations in the level of skill within occupations, economies, and/or over time. For analysis of changing skills levels over time, the historical example of craft workers often stands as a benchmark.

Although skill has always been a somewhat ambiguous and rarely precisely defined term, in the past it had a much narrower meaning than today. It tended to be equated with craft, technical know-how, and manual dexterity. Gradually, however, the importance of mental qualities was acknowledged and motor skills and cognitive skills were distinguished. While motor skills require voluntary body movement to achieve a goal, cognitive skills do not involve muscular movement and involve activities such as problem solving, memory, or reading (Tomporowski 2003). More recently, the concept of skill was further broadened. In addition to "hard skills" (both motor and cognitive), the importance of "soft skills" was underlined. They include effective communication, creativity, flexibility, change readiness, leadership, team building, and so on. Much discussion has also been given to the distinction between "generic" (also "transferable" or "key") skills on the one hand and occupational or job-specific skills on the other. While occupation-specific skills have value only in one particular sector or industry, generic skills have value in a number of sectors. The tendency to re-label as skills personal traits and attitudes and to term many concrete and abstract human dispositions as "skills" further broadened and blurred the concept.

Theories

In social theories, the concept of skill is usually linked to the labor market, education, and technology. Authors, however, differ fundamentally on the role skills are supposed to play. The origins of the skill concept are often connected with Karl Marx. The dominant interpretation of Marx's work suggests that capitalists, through mechanization of labor and the manufacturing system, reduced skills requirement to increase productivity and profits and to increase control over workers and work organization. This line of reasoning was followed in so-called de-skilling theory, assuming a process of job degradation (Braverman 1974). In sharp contrast, the thesis of postindustrial and/or knowledge societies posits a general upgrading of skills and stresses the growing importance of cognitive skills. Human capital theory also stresses the importance of knowledge and skills to economic performance and assumes that employers adjust earnings to reflect both skills and educational attainment. Workers with scarce skills are supposed to obtain better-paid and more secure jobs than those without them, and skills and education are assumed to be highly correlated. In contrast, credential theory (Collins 1979) views education as a biased indicator of skill and asserts that colleges function more as a rationing device in job allocation than as skills provider. Educational credentials are supposed to be a much more important determiner of labor force reward than skill.

Theoretical positions also differ in the extent to which skill level is supposed to be objective or socially constructed (Spennier 1990). Neoclassical demand-side perspectives (for example, the theory of the firm) as well as supply-side perspectives (such as human capital theory) tend to take the nature of skills as objective, determined by market mechanisms and the logics of efficiency and return on capital. An opposing view is that skill level is not an objective phenomenon but a social construct. Occupations and jobs are labeled as skilled, semiskilled, or unskilled on the basis of custom and practice, such as union negotiation or job regulation. The most direct method of enhancing an occupation's power is to remove...
itself from market competition (so-called social closure), establishing a monopoly over some tasks and thus gaining the ability to increase the price of services and therefore prestige (Attewell 1990). Occupations that can restrict entry, require a lengthy period of training, and remove themselves linguistically from lay language (consider Latin in medicine or slang in many professions) can create a public perception of work that requires exceptional knowledge and skill. In contrast, certain types of work may thus objectively require a high level of technical skill but go unrewarded in the labor market.

**APPROACHES TO MEASUREMENT**

From the epistemological point of view, positivists and ethnomethodologists can be determined (Attewell 1990). Positivists treat skill as an attribute that has an objective character independent of the observer and is amenable to more or less objective measurement. They also reflect the Cartesian division of intellect and body and regard the former as superior. Skill is acquired when one achieves knowledge about general and abstract principles and rules that are context free. Not surprisingly, they take cognitive skills, especially the most complex and abstract ones, as higher-level skills. In sharp contrast, ethnomethodologists suggest that all human activities, even the most mundane such as walking or carrying on a conversation, are quite complex and require a complex coordination of perception, movement, and decision. Because these mundane activities are extraordinarily complicated, they cannot be attended consciously. Conscious reflection of activity is thus an indication of incomplete learning rather than mastery. Skill means the ability to do things without thinking about them. A master’s skills are not based on conscious, abstract, and context-free knowledge but rather on tacit and context-bound knowledge. In consequence, ethnomethodologists consider abstract rules as being at a much lower level of skill and challenge positivist and quantitative approach to measuring skills.

Empirical research on skills usually follows the positivist approach. Based on the distinction between skill as an individual competence and as a job requirement, skill supply and skill demand measures are usually distinguished. Both skill supply and skill demand can be measured both directly and indirectly. As for skill demand (that is, skill requirements of jobs), direct measures involve (1) job classification based on some kind of external judgment, and (2) self-reported (by the jobholder) requirements. Indirect measures include the average or typical education among job incumbents. Because of lack of data, many researchers use indirect measurement or infer skill demand from data on skill supply (usually education) and wages. This approach, however, has an important limitation—it conflates the supply and demand sides of skill (workers and jobs). Many studies have found that education, skill, and labor reward are not equivalent concepts and that their interchangeability precludes testing of the various theories stated earlier. Thus, direct measures of skills requirements, though not without problems, are preferred. The most widely used direct measures of skill demands are occupational schemas, such as the American Dictionary of Occupational Titles (DOT). As for skill supply (workers’ skills), only indirect measures are usually available. These include the sum of years of vocational or formal education, years of on-the-job experience, or wage rates. In the 1990s large-scale international surveys such as International Adult Literacy Survey (IALS) were introduced, allowing direct and international measurement of cognitive skills (OECD 2000).

**IMPLICATIONS**

The concept of skill must be always used with care, and one must bear in mind that different theoretical approaches define and measure skills in quite different ways, especially since skill theory and measurement have several fundamental and direct policy implications. From the policy point of view it is important to know (1) whether capitalism and/or new technologies are deskilling or up-skilling work, how skills needs change over time, and what skills will be needed in the future; (2) how much (and what type) of education is needed in the labor market and what causes skills mismatches; (3) to what extent unequal labor force rewards are determined by education, skills, or discrimination; (4) how skills are distributed within and between countries, and whether the distribution is increasingly polarized; (5) how skills are created in different education and training systems; (6) how to measure and classify skills in a standard way to ensure labor mobility and qualification recognition; (7) what type of skills are needed in nonmarket relationships, such as family or community; and (8) to what extent education should provide students with generic or specific skills. Because the concept of skill is difficult to define and started to be measured directly only very recently, it is not possible to give a definite answer to any of these eight questions. Analyses done so far (e.g., Kerckhoff, Raudenbush, and Glennie 2001), however, confirmed that skill is not a redundant term but an empirically independent factor, one that needs to be taken as a separate theoretical construct.

SKINNER, B. F.  
1904–1990

B. F. Skinner, an American psychologist, provided the experimental foundations of contemporary behavior analysis and its applications. He introduced the terminology of operant behavior and elaborated on the concept of reinforcement. He interpreted verbal behavior in terms of those foundations and was outspoken about the differences between the methods of behavior analysis and those of cognitive psychology. His contributions provided the foundations for extensions to a variety of applications both within and outside of psychology (e.g., education, psychopharmacology, behavioral economics).

Born on March 20, 1904, in Susquehanna, Pennsylvania, Burrhus Frederic Skinner (later known mostly as B. F.) grew up while the inventions of Thomas Edison and others were changing life in small-town America. From an early age, Skinner was a tinkerer, building gadgets and devices. At Hamilton College, he majored in English, also taking courses in science and philosophy. He sent some short stories to Robert Frost after graduation. Frost’s reply encouraged him to take a year off from academic pursuits to try a career in writing. But Skinner concluded that he had nothing to say and called the time his “dark year.”

Having read Pavlov and others, Skinner turned from English to psychology and entered the doctoral program at Harvard University, where he began experiments on the behavior of rats that led to more than two dozen journal articles and culminated in his 1938 book, *The Behavior of Organisms*. In 1936 he moved to the University of Minnesota, where he continued basic research. World War II occasioned a project on training pigeons to guide missiles that got only to the point of a demonstration of feasibility, but a fringe benefit was the discovery of shaping, a technique for teaching new behavior. One other consequence was that pigeons began to replace rats as the dominant organism of the operant laboratory.

Another product of those days was the Aircrib, which Skinner built for his wife and second daughter. The windowed space with temperature and humidity control improved on the safety and comfort of ordinary cribs while making child care less burdensome. Rumors to the contrary, it was not used for experiments with the infant. Skinner noted that there was nothing natural about standard cribs; he had simply invented a better one.

In 1945 Skinner became Chair of the Department of Psychology at Indiana University. After his 1947 William James Lectures at Harvard University, on verbal behavior, he returned permanently to Harvard. His 1948 novel, *Walden Two*, which at first received little notice but later became widely read, described a utopia the most important feature of which was its experimental character: Any practice that did not work was to be modified until a more effective substitute was found.

Meanwhile, at Columbia College, Fred S. Keller and W. N. Schoenfeld created an undergraduate psychology curriculum based on Skinner’s work, including a one-year introductory course with a laboratory. With research now located at several universities, meetings of those interested in behavior analysis became a series of annual conferences. Eventually a formal division for the Experimental Analysis of Behavior (Division 25) was established within the American Psychological Association. During those years, while the Harvard Pigeon Laboratory provided students of operant behavior opportunities to develop their own independent lines of research, Skinner created the subject matter of reinforcement schedules in collaboration with Charles B. Ferster and built the first of his teaching machines. Soon after, Keller began his innovations in college teaching that introduced self-paced courses and behavioral definitions of teaching objectives. The *Journal of the Experimental Analysis of Behavior* began publication in 1958; within a decade, the increased activity in applications of operant theory led to a companion journal, the *Journal of Applied Behavior Analysis*.

In 1953, in his book *Science and Human Behavior*, Skinner dropped the formal structures of his early theorizing, modeled after theory in the physical sciences, and made the ties to biology explicit in his many references to evolutionary contingencies. He also began explicitly to extend the principles of his early research to human behavior. Here were treatments of self-control as competition between short-term and long-term contingencies involving consequences of different magnitude, of think-
ing as covert behavior, of reports of private events as verbal behavior shaped by verbal communities that had access only to public correlates, of social behavior, and of selves as functionally organized systems of responses. There was hardly a significant aspect of human endeavor that was not captured in one way or another by the net that Skinner had so widely cast.

Skinner retired from the laboratory in 1962, returning to it only briefly nearly 20 years later, but continued his writing throughout his life. His books include the controversial *Beyond Freedom and Dignity* in 1971, *About Behaviorism* in 1974, and a three-volume autobiography. *In Beyond Freedom and Dignity*, Skinner pointed out that some controversies about freedom result from confusions between two sources of the language of freedom. The issue of freedom versus determinism is a philosophical question with a long history, but the issue of freedom from coercion is an empirical problem that involves the consequences of various social and political practices. In our daily lives, we are typically concerned not so much with whether our choices are determined as with how our choices are determined and by whom. Doing something at the point of a gun is different from doing it under other circumstances.

Skinner learned of his leukemia in 1989. On August 10, 1990, at his final public appearance, he accepted a Lifetime Achievement Award from the American Psychological Association. His remarks criticized cognitive science as the creationism of the twentieth century, in that it sought causes of behavior inside the organism instead of in the organism’s environment. A week later, in hospital, Skinner put finishing touches on his last journal article, “Can psychology be a science of mind?,” for the *American Psychologist*. He died the next day, August 18, 1990. His last word, upon receiving a drink of water, was “Marvelous.”

**THE ANALYSIS OF BEHAVIOR**

Skinner followed Pavlov in insisting on the primacy of data and the study of individuals rather than groups but diverged from Pavlov in many ways. For Skinner, behavior was not to be taken as a symptom of something else. As interaction between organism and environment, it should be studied in its own right, not to resolve problems of physiology or to open the way to cognitive or other levels of analysis. Skinner did not disapprove of physiology but argued that without a science of behavior neuroscientists would not know what to look for in the nervous system.

In Pavlovian conditioning, a conditional stimulus comes to produce responses related to those elicited by an unconditional stimulus. The prototypical example is the elicitation of salivation by some stimulus that consistently precedes food. In Skinner’s operant behavior, the contingencies are different: A stimulus sets the occasion on which responses have some consequence; absent that stimulus, responses do not do so. The prototypical example is the rat whose lever presses produce food only in the presence of a light. The rat comes to press the lever only when the light is on. Such stimuli, colloquially called signals or cues, do not elicit responses; instead, they set the occasions on which responses have consequences. Such behavior, called operant because it operates on the environment, does not entail associations or stimulus-response connections. The three-term contingency, in which stimuli set the occasion upon which responding has consequences, is not reducible to pair-wise stimulus and response relations.

Here was a profoundly simple concept: The consequences of current behavior reinforce or select the behavior that will occur later. Associationism had been replaced by selectionism. Reinforcement operates on populations of responses within individual lifetimes much as evolutionary selection operates on populations over successive generations in Darwinian natural selection. The populations, operants, are classes of responses defined by their effects rather than by what they look like (Skinner also considered implications of a third variety of selection, sometimes called cultural or memetic selection, that occurs when behavior is passed on from one organism to another, as in imitation).

Shaping, which creates novel behavior through reinforcement of responses that successively approximate it, illustrates reinforcement as selection. For example, if the strongest of a rat’s initially weak lever presses are reinforced, the force of pressing increases and the reinforcement criterion can be moved up to the strongest of the new population. With continuing force increases and criterion changes, the rat soon presses with forces that would never have been observed without shaping. Shaping opened up education, developmental disabilities, behavioral medicine and even the training of pets to applications of behavior analysis. When research produced variable results, solutions were sought not by averaging over more subjects but by refining procedural details to identify sources of variability. The applied analysis of behavior is recognized for both effectiveness and accountability; treatment of early autism is among its several notable successes.

The discovery that behavior could be maintained easily even when responses were reinforced only occasionally led to schedules of reinforcement, which arrange reinforcers based on number of responses, the times when they occur, or various combinations of these and other variables. Different schedules produce different temporal patterns of responding. A device that Skinner called the
cumulative recorder allowed these temporal patterns to be visualized in considerable detail. Schedules are now used widely in studies ranging from psychopharmacology to behavioral economics.

VERBAL BEHAVIOR
In his 1957 book, *Verbal Behavior*, Skinner extended his analyses to the functions of words. His approach differs from linguistics, the study of language, in that linguists describe practices of verbal communities in terms of the grammars, vocabularies, and phonetic units characterizing different languages; these descriptions of language structure tell little about their functions. This behavioral distinction is analogous to that between physiology (function) and anatomy (structure) in biology. Behavior analysis, following from Skinner's work, deals mainly with function (i.e., how does behavior work, what does it do), whereas cognitive science deals more often with structure (e.g., organization in what is perceived or learned).

Skinner's book was mainly about language function. A critical 1959 review by the linguist Noam Chomsky was more concerned with language structure than with the functional content of Skinner's account. *Verbal Behavior* provided a taxonomy of function rather than structure (for example, identifying verbal classes by their effects rather than by their topographies), applying it to a broad range of verbal phenomena. Later expansions extended the taxonomy to the origins of novelty in verbal behavior. Skinner did not reply to Chomsky's review because it had missed the point, but unfortunately some interpreted his failure to reply as a sign that he could not do so. Skinner and others addressed Chomsky's review only long after.

One function of verbal behavior is instruction; people often do things because they are instructed to do them. Following instructions has social consequences and is crucial to many social institutions—families, schools, industry, the military—so it is important to understand not only how instructions work but also how they can go wrong (e.g., as in following unethical orders without question). Skinner called behavior that depended on words rule-governed behavior, though it is now more often called verbally governed behavior. In verbal governance, what we say about what we do often determines what we do. Contemporary analyses of verbal behavior include experimental studies of how verbal governance comes about and the conditions under which it occurs.

BEHAVING AND KNOWING (BEHAVIOR AND COGNITION)
Skinner's analyses were also about how we come to know ourselves. We think we have privileged access to private events such as feelings and thoughts, but how do we learn to talk about them? Parents who see the colors that a child sees can respond appropriately to the child's color naming and so can teach the names, but how can a verbal community without access to relevant stimuli create and maintain verbal responses? In referred pain, a bad tooth in the lower jaw may be reported as a toothache in the upper jaw; here the dentist is a better judge than the patient of where the bad tooth really is. If we can be mistaken even about the location of a toothache, how can other reports of private events be reliable?

Skinner did not deny the private, but noted that common vocabularies can be based only on what is mutually accessible to both speakers and listeners. If private feelings do not have public correlates, how can one tell when anyone else has them? If one cannot tell, how can one ever teach appropriate words? This is a problem because much of the language of cognitive thought originates in the vocabulary of private events.

According to Skinner, processes called cognitive (e.g., thinking, visualizing) are kinds of behavior. Skinner did not deny events taking place inside the skin, but maintained that they should be called private rather than mental. When Skinner criticized representations in cognitive psychology, the issue was not whether lasting effects are produced by stimuli (an organism that has responded to a stimulus is a changed organism). Rather, it was about the form the change takes. Skinner opposed copy theories of behavior or perception. A representation is not necessarily a copy (a spoken letter may represent a seen one but has no visual properties in common with it), so it is of interest that the most successful cognitive accounts do not involve representations that function as copies. In this regard, behavior analysis shares its views with cognitive scientists who are advocates of neural nets and connectionist systems.

SKINNER BOX

In behavioral studies, researchers study the relationship between environmental events and measures of a target behavior, termed a respondent (in classical conditioning) or free operant (in operant conditioning). In the 1930s, as B. F. Skinner was developing the laws of operant conditioning, he constructed an apparatus, technically called an operant chamber but popularly known as a “Skinner box,” that deprives an animal of all external stimuli other than those under the control of the experimenter (Skinner 1935). Generally, a Skinner box is soundproof and light-resistant, and usually contains a bar or lever to be pressed by the animal to either gain a reward or avoid a painful stimulus. An operant chamber allows the researcher to experimentally manipulate environmental stimuli and measure their impact on operant behavior. Additionally, the use of the chamber allows data on the animal’s responses to be monitored and collected electromechanically twenty-four hours a day, seven days a week, thus eliminating the need for an external observer to record behavior.

Employed for more than seventy years in basic operant research, the operant chamber recently has been used to study topics such as how previous conditioning influences the acquisition of new responses under delayed and immediate reinforcement (Snycerski, Laraway, Huitema, and Poling 2004); discrimination training (Nevin, Davison, and Shahan 2005); how drugs affect responding (Pinkston and Branch 2004); concurrent schedules (Sealey, Sumpter, Temple, and Foster 2005); and sophisticated data analysis techniques (e.g., Li and Huston 2002).

Although there have been organized contests to train a rat to complete a series of complex activities using live animals and an operant chamber (Banister-Marx 1996), maintaining an animal laboratory with operant chambers is expensive, and often beyond the resources of those not engaged in ongoing research programs. As a result, researchers have developed software such as “Sniffy the Virtual Rat” (Alloway, Willson, and Graham 2005) to simulate how schedules of reinforcement and extinction effect responding. Another software simulation program allows students to learn to modify a bird’s behavior (Hay 2004). Nick Yee suggests that role-playing games such as “EverQuest” have all the elements of a virtual Skinner box (2001a, 2001b).

The Skinner box is sometimes confused with the baby tender, a device Skinner developed to provide one of his infant daughters with a comfortable, protective environment in which to sleep (Skinner 1945). The rumor that Skinner left his infant daughter in the device for such long periods of time that she was traumatized and later committed suicide in her twenties is completely untrue—in fact, Deborah Skinner Buzan wrote an article in 2004 about the myth (Buzan 2004). Nevertheless, the story has continued to circulate and is included in an historical account of major events in psychology (Slater 2004).

SKOCPOL, THEDA
1947–

Victor S. Thomas Professor of Government and Sociology and director of the Center for American Political Studies at Harvard University, Theda Skocpol was president of the American Political Science Association (2001–2003) and of the Social Science History Association (1996). She has made major contributions to historical and comparative sociology and to political science in her work on revolutions. Her theory of revolutions and the state has been influenced by the approach of sociologist and political scientist Barrington Moore (1913–2005) in his Social Origins of Dictatorship and Democracy (1966).

In Vision and Method in Historical Sociology (1984), Skocpol advocated the use of secondary data and sources to undertake macrohistorical and comparative work—an approach that she pioneered in her major work, States and Social Revolutions: A Comparative Analysis of France, Russia, and China (1979), which received the C. Wright Mills Award of the Society for the Study of Social Problems, as well as the American Sociological Association Award for a Distinguished Contribution to Scholarship. With this work, Skocpol produced a distinctive theory of revolution through the study of three anciens régimes. Skocpol argued that revolutions occur because states are exposed to endogenous socioeconomic processes, particularly class conflict. Her theory rejects any significant role for human agency in such revolutions. They are not produced by the revolutionary will of revolutionaries themselves, but they are the unintended consequence of the decomposition of the state system and its agrarian bureaucracy. Skocpol examined the causal constraints—class relations, the repressive character of the state, and the external military—on state activities resulting from objective historical circumstances. The distinctive aspect of her initial theory was to reject any attempt to absorb the state into society, since the repressive actions of the state have independent causal consequences for revolutions.

Skocpol’s “state autonomy theory” was severely criticized by G. William Domhoff (1996), who claims that she abandoned her original position, increasingly putting emphasis on social movements, women’s lobby groups, and voluntary associations in civil society. By contrast, Domhoff argues that support for disability pensions for Civil War veterans is explained by the interests of the corporate community (or capitalists). The differences between welfare provision in the United States and Europe is explained by the strength of the American capitalist class and the racial and ethnic divisions in the American working class.

SLAVE LIVES, ARCHAEOLOGY OF

The archaeology of slavery is a branch of historical archaeology focused on the analysis and interpretation of slavery through the use of material remains. The archaeology of slavery was originally referred to as plantation archaeology because the excavations were concentrated on former plantations throughout the southern United States. In the early days of plantation archaeology, the primary focus was on the maintenance and promotion of nationally significant historic sites; however, as a result of a movement to develop a deeper understanding of ethnicity and diversity within American society, in the late 1960s there was a shift in the field to include a broader understanding of the lives of enslaved Africans. Archaeological studies of slavery provide information on the living conditions of enslaved people by looking at housing and household composition, diet, personal possessions, household goods, health care, and other aspects of their material world. This subset of historical archaeology is used to understand the human experience of African American life and positively contribute to the ever-expanding notion of black cultural identity. Although the first archaeological sites that
focused on slavery were in the southern United States, there has been a great deal of work conducted in other parts of the African diaspora, including such regions as Central and South America and the Caribbean.

THE ARCHAEOLOGY OF RACE AND GENDER

Early archaeological interpretation took its lead from traditional history. Much of the analysis was based on the search for general patterns that reinforced accepted notions of the experience of slavery. These early sites highlighted archaeology as a method to fill in the gaps of historical analysis with the use of artifacts. The archaeology of slavery, however, shifted from a general perspective of plantation life to the examination of specific enslaved communities.

The archaeological study of plantations has begun to employ an anthropological methodology known as critical theory. As an ideology, critical theory encourages movement beyond the boundaries of academia into the community. Critical theory is an approach that engages contemporary social issues in various ways. The form of critical analysis used in the archaeology of slavery is a form of activist archaeology that recognizes and supports the role of descendant communities in order for them to retrieve histories from their own perspectives. The archaeology of slavery has become much more visible to the public, and the interpretations and contributions the field makes take into consideration groups of people traditionally marginalized.

The shift toward a more collaborative research methodology that allows archaeology to become a respected voice in public discourses about contemporary notions of race and racism was a direct response to the events surrounding the African Burial Ground project in New York City in the early 1990s. The political struggles between the local African American community and archaeologists marked a turning point in the relationship between the archaeological community and the public. The practice of engaged or activist archaeology became synonymous with the field as a result of this site.

In an effort to understand the lives of enslaved communities, archaeologists investigate the multiple meanings of environment and space. Plantation landscapes often include areas of domestic production, also known as slave quarters, and other sites where the everyday activities of enslaved communities took place. These household-related activities included basic food preparation, childcare and health care, laundry, clothing repair, recreational storytelling, music making, and game playing. These quartering areas ultimately became sites to strengthen social relationships and ensure the survival of the enslaved community.

In 2001 Maria Franklin first proposed a black feminist archaeology that would contribute to a deeper analysis of multiple forms of oppression and pay closer attention to the role of gender by highlighting the unique experience of enslaved women. A black feminist approach emphasizes how gender and race affect a specific community. This approach also demystifies contemporary misconceptions of the role of enslaved women within the household, taking into account the fluid nature of the enslaved family and alternative ways to understand how enslaved women were integral yet not solely responsible to black cultural production. When archaeological investigations of plantation societies during the colonial and antebellum period have focused on households, there is an emphasis on spaces dominated by women. However, enslaved communities performed domestic tasks communally. A gendered approach identifies how enslaved women played an essential role in social and cultural reproduction and acknowledges the role of gender and race in analyzing the multiple forms of oppression experienced by all members of the enslaved community. The result of this methodology inherently serves as a means to produce holistic and politically aware accounts of the African-American past.

ATLANTIC AFRICA AND THE AMERICAS: AFRICAN DIASPORA ARCHAEOLOGY

The archaeology of the African diaspora has expanded the scope of research and established a dialogue between Africa and the Americas during the slave trade era. This dialogue has allowed for a comparative and transnational methodology that produces a new direction in the archaeological interpretation of slavery. Current trends in African diaspora archaeology acknowledge the complexity of how Africans in the Americas negotiated their identities and incorporated aspects of African culture in the African experience throughout the diaspora. Archaeologists also recognize ways in which the diaspora influenced the continent of Africa. Archaeologists therefore, are considering the global dimensions of African cultural transformations throughout the modern era.

The social memory of people of African descent is linked to the experience of slavery, from the way a community shaped its built environment, the material remains of social and cultural activity, and how the distant past acts as the foundation of contemporary notions of black identity. The artifacts, architecture, and archaeological deposits at different sites allow for a close and unique way of looking at the institution of slavery. The archaeology of slavery has moved beyond the boundaries of plantations in the southern United States. After more than twenty years of excavations, the conversation between
archaeologists working in the Caribbean, United States, and Western Africa has resulted in an enhanced study of the system of slavery. These links are essential to the future of the field; the things that have been shared between sites across the diaspora and continental Africa have led to a more holistic approach to the study of African people.

SLAVE MODE OF PRODUCTION

Although one of the least developed Marxist concepts, slave mode or organization of productive relations has spawned rich intellectual debate. There are four major lines of inquiry. Must the number of productive workers be the dominant form of labor? What is the significance of surplus extraction (profit through exploitation) in the organization of production, and how does it define a social formation? Is there one mode of production or several competing social formations at any one time? What was the historical evolution of the slave mode of production?

Although Karl Marx’s primary concern was with the historical evolution of capitalism, not pre-capitalist social formations, he occasionally referred to the slave mode of production. The German Ideology identified the first historical form of property as communal, containing within it familial and slave relations (1978, p. 151). The Communist Manifesto recognized three forms of class society: capitalist and proletarian during the bourgeois epoch, lord and serf during feudalism, and master and slave during antiquity (1978, p. 474). The Grundrisse described the second system of historical development as antiquity characterized by dynamic, urban, warlike conditions, with chattel-slave relations (1965, pp. 36, 71–75). Despite these references, Marx provided little conceptual explanation for the origins and nature of slavery. In contrast to his analysis of the conditions of modern capitalism, he gave little attention to the internal dynamic of the slave mode of production and how this mode rises out of past social formations and dissolves under new historical conditions.

SLAVES IN ANTIQUITY

Unlike Marx, scholars of antiquity have long debated the nature of classical slavery. According to Moses Finley, slavery was insignificant both temporally and geographically in the Greco-Roman world. The dominant labor force produced under various degrees of “unfreedom” in a society with different relations of production. The key question, concludes Finley, is “whether the relations of production were sufficiently different to preclude the inclusion of such societies within a single social formation in which the slave mode of production was dominant” (1991, p. 496). On the one hand, Ellen Meiksins Wood argues that peasant-citizens rather than slaves constituted the productive basis of Athenian democracy and that forms of tenancy, leasing, and management, not slavery, formed the basis for surplus extraction (1988, pp. 64–82). Geoffrey E. M. de Ste. Croix agrees that non-slave producers accounted for the demographic majority during antiquity, but argues that the dominant form of exploitation was slavery because slaves provided the surplus extraction for a wealthy elite. According to Ste. Croix, Marx’s concentration on the distinctive feature of society “is not the way in which the bulk of the labour of production is done, but how the extraction of surplus from the...
immediate producer is secured” (1981, p. 52). It was slav-
ery’s increase in surplus extraction that accounts for “the
magnificent achievements of Classical civilization” (1981,
p. 40). Perry Anderson agrees on the importance of slave
surplus extraction during antiquity, although he argues that
the imperial state played a more important role in organiz-
ing the actual process of extraction (1992, pp. 19–22).

Another key question concerns the historical evolu-
tion of ancient slavery into new social formations. Marx
simply described the movement of “progressive epochs in
the economic formation of society” (1978a, p. 5). In con-
trast, Ste. Croix explains that slavery was the most efficient
form of surplus extraction was transformed once Roman
frontiers stabilized and the number of war-supplied slaves
tailed off. The consequence was increased slave-breeding
as landowners sought to maintain their labor force. The
crucial factor was female slave reproduction over slave
production. To make up for the lost surplus, landowners
extended exploitation to hitherto free laborers, with the
result of the emergence of a uniform class of coloni whose
rate of exploitation was down, but volume had expanded.
Thus, the ancient world was destroyed by a social crisis
from within and finished off by the so-called barbarians
from without (1991, p. 503). Anderson agrees on the
internal social crisis but pays equal attention to external
factors. “The dual predecessors of the feudal mode of pro-
duction,” he argues, “were the decomposing slave mode of
production on whose foundations the whole enormous edifice of the Roman Empire had once been constructed,
and the distended and deformed primitive modes of pro-
duction of the Germanic invaders” (1974, pp. 18–19).

NEW WORLD SLAVES

Although Marx’s own historical moment was dominated
by the capitalist mode of production, slavery was not a
peculiar institution in the mid-nineteenth century. When
Marx was forty-two years old in 1860, there were about
six million enslaved Africans in the New World, two-
thirds of whom were imprisoned in the American South.
Numerous scholars have debated this duality. Eugene
Genovese argues that southern slavery was in conflict with
capitalism and created a “powerful and remarkable social
class” (1967, pp. 3–4). In contrast, John Blassingame has
focused upon slave non-productive relations, especially
communal and cultural formations. Other scholars insist
on the centrality of productive relations. Ira Berlin and
Philip Morgan insist that work “engaged most slaves, most
of the time” (1993, p. 1). Still others insist on the
exploitative nature of slavery and the role of surplus
extraction. Eric Williams argued that slavery built up cap-
italism, while capitalism destroyed slavery. Robin
Blackburn has recently argued that the profits from colo-
nial slavery's surplus extraction—what he dubs “extended
primitive accumulation”—fueled Britain’s remarkable
industrial takeoff. The passage from pre-modern to mod-
ern society was not that of the classic Marxist transforma-
tion of agrarian property relations, but rather “exchanges
with the slave plantations helped British capitalism to
make a breakthrough to industrialism and global hegemon
ahead of its rivals” (1997, p. 572). Unlike economic
arguments for the shift from antiquity to feudalism, polit-
ical explanations for passages from slavery to modernity,
especially slave revolts in the New World, have been per-
suasively made by W. E. B. Du Bois, C. L. R. James,
Robin Blackburn, and others.

SLAVES IN AFRICA

The debates on slave surplus extraction, competing social
formations, and historical evolution have been extended
to Asia and Africa. Walter Rodney argues that there
was no “epoch of slavery” in pre-fifteenth-century Africa
because of the absence of “perpetual exploitation.” He
prefers the notion of competing social formations to one
mode of production with pre-colonial Africa in transition
from communal agriculture to feudalism (1982, p. 38).
Claude Meillassoux agrees that the absence of perpetual
“relations of exploitation and the exploiting class” ensured
there was no system of slavery in Africa and that there
were several social formations (1991, pp. 36, 235). But he
goes further. Slavery was not only a relationship of pro-
duction, but also a “mode of reproduction” (1991, p.
324). In contrast to Ste. Croix’s argument for antiquity,
this reproductive slavery had little to do with procreation
and much more to do with the economy of theft through
of capture and markets,” Meillassoux argues, “had their
counterpart in the sterility of the women slaves who,
despite their sex and their numbers, were deprived of
reproductive functions” (1991, pp. 85, 278). Although
John Thornton does not subscribe to Marxist concepts
such as mode of production and surplus extraction, he
does insist on the centrality of slavery to the continent’s
historical development, and his argument has been quite
influential. Specifically, ownership or control of labor (in
contrast to land ownership in feudal Europe) was the
dominant principle of property relations in African soci-
eties, and “slavery was rooted in deep-seated legal and
This view has been correctly criticized for downplaying
the qualitative change wrought by the advent of the
Atlantic slave trade.

Returning to the lines of inquiry above, there are
some key points. The number of productive workers does
not have to be dominant. This was as true of slaves in
antiquity as of slaves in the New World. Surplus extrac-
tion is critical to particular social formations.
Slaves in antiquity and the New World helped build magnificent civilizations. Slavery is a modern as well as an ancient social formation. Kevin Bales counts twenty-seven million slaves today operating as part of the global economy (1999, p. 9). Slavery plays a role in the historical evolution of social formations in terms of both reproduction and production. There is no one passage from slavery into other social formations.

**SLAVE RESISTANCE**

Demographic realities and power relationships in the British mainland colonies and later, following independence, in the United States, militated against the type of large-scale slave conspiracies that took place in South America and the Caribbean. The presence of a heavily armed white majority in every state except South Carolina (and, toward the very end of the antebellum period, Mississippi), the lack of an impregnable hinterland in which to create maroon colonies from which runaways could besiege plantations, the relatively dispersed nature and small size of slaveholding, and the fact that the landlord class was in residence (not absentee) combined to make massive slave rebellions far less common than day-to-day resistance or individual acts of self-threat. In the years after the Revolution, as harsher forms of colonial paternalism began to metamorphose into paternalism—a complex and ongoing process of negotiation and brutality that many scholars regretfully reduce to a simplistic model of accommodation—slaves achieved enough living space to build stable families and rich spiritual communities. Given the odds against success, it is hardly surprising that the handful of slaves bold enough to rise for their freedom found their rebellions reduced to unsuccessful conspiracies and their fellows doomed to die in combat or on the gallows.

Despite persistent attempts by historians to force a uniformity of vision and goals on rebel leaders, insurgent slaves in the eighteenth and nineteenth centuries differed from one another fully as much as white revolutionaries in the same era. Jemmy, an Angolan who led an agrarian uprising in 1739 near Stono River, South Carolina, tried to hasten his African followers across the border into Spanish Florida. Caesar Varick, who only two years later in 1741 conspired to burn New York City, lived in one of...
North America’s largest urban centers with an Irish wife. Gabriel, a young, secular rebel who had turned away from African traditions, hoped to stay and work in a more egalitarian Virginia. Denmark Vesey, an aged free black who bought his freedom the year before Gabriel died in 1800, expected to achieve a limited exodus for his family and followers out of Charleston to Haiti. Vesey and his chief lieutenant, “Gullah” Jack Pritchard, an East African priest, fused African theology with the Old Testament God of wrath and justice, whereas Nat Turner relied on Christian millenial themes and hoped to bring on the day of jubilee for black Virginians. Beyond their obvious abilities as leaders and their equally obvious desire to breathe free, bond rebels in the United States fit no simple pattern.

If slave rebellions in North America correspond to any one model, it is that they proliferated during times when the white majority was divided against itself in significant ways. Colonial insurgents in South Carolina and New York City turned to violence at a time when their masters were at war with France and Spain. Gabriel, the most politicized of all the slave rebels, formulated his plans during the divisive election of 1800, when Federalists and Republicans threatened to take up arms against one another. The rebels in the Tidewater area of Virginia, despite the memory of the repression that followed Gabriel’s death, began to organize again during the chaos of the War of 1812. Having read of the Missouri debates in Charleston newspapers, Vesey prayed that northern whites would prove tardy in riding to the rescue of the estranged Southerners. Slaves near Natchez, Mississippi, began to plan for their freedom in 1861, following the outbreak of the Civil War.

Most of all, slaves, who well knew what they were up against and rarely contemplated suicidal ventures, plotted for their freedom only when safer avenues had been closed to them. For most of the seventeenth century, for example, when the high death rate in the Southern colonies made inexpensive white indentured servants far more numerous than costly African slaves, enterprise bondpersons relied more on self-purchase than the sword. The economic possibilities in early Virginia produced more runaways than rebels; the practice of buying one’s own body even produced several black entrepreneurs—such as Anthony Johnson, a former slave who became a wealthy planter and who named his estate Angola after the land of his birth. It was only after landless whites and hard-used white indentured workers under the command of Nathaniel Bacon burned Jamestown in 1676 that Southern planters made a concerted effort to replace white servants with African slaves. The comprehensive Virginia Slave Code of 1705, the first of its kind in colonial North America, crushed the hope of industrious slaves that they might be upwardly mobile. Only then, as North American racial walls rapidly hardened, did desperate slaves turn to physically hazardous paths toward freedom. During the last days of Queen Anne’s War in April 1712, a determined band of twenty-five Coromantee Africans burned several buildings in New York City and killed nine whites. (Unfree labor had been legalized in New York by the Duke’s Law of 1665.) Having made a commitment to unfree labor, equally determined whites revenged themselves on the rebels. Several rebels committed suicide before they could be captured, but those taken alive were broken on the wheel and hanged in chains as a warning to future rebels.

In the early eighteenth century, even though the constant threat of war between Britain and its continental neighbors provided endless opportunities for daring slaves, mainland revolts rarely posed much real danger to the slaveholding regime. Because the Atlantic slave trade was at its peak, every colony included large numbers of native Africans who sought to escape from bondage by building isolated maroon communities. Most runaways fled into the hinterland, where they established maroon colonies and tried to re-create the African communities they had lost. Even the two most significant rebellions of the period—that of Stono, South Carolina, and the subsequent attempt to burn New York City—were led by Africans who dreamed only of ending their own bondage, not of ending unfree labor in general. Aware of Spanish promises of freedom in colonial Florida, Angolan soldiers under Jemmy tried to escape across the border. To the north, New York City bondmen planned to torch the wooden city and flee to French Canada, which was then at war with the rebels’ masters. The price of failure was high. New York authorities ordered Caesar Varick and twelve of his followers burned alive; eighteen others were hanged—two of them in chains—and seventy more bondmen were banished from the colony.

Given the odds against them, most enslaved men and women resisted their condition through other methods. Young men, especially those who had not yet married, ran away, often in homogenous groups. Before the early nineteenth century, slaves in the Southern colonies fled toward Spanish Florida, while those in the North sought freedom in French Canada; with the gradual emancipation of slavery in the Northern states and the American acquisition of Florida, bondmen journeyed toward the free states or remained truants within the South. Some women, particularly domestic servants, occasionally fought back through poison. Although it is hard to know whether the illness of white masters was due to toxins or natural causes, colonies like South Carolina passed legislation in 1751 against “the detestable crime of poisoning [that] hath of late been frequently committed by many slaves” (Rucker 2005, 112).

The onset of the American Revolution alternately discouraged and stimulated slave rebellions. Although the
British invasion and the animosity between patriots and Tories presented slaves with a unique opportunity to organize, most slaves chose instead to take advantage of the dislocation of war to escape with their families into the growing cities or behind British lines. (The Revolution was the one time in North American history when as many female slaves as males ran away.) Because the aggressive bondmen who cast their lots with the military forces of King George were precisely the sort of bold, determined slaves who normally tended to organize slave conspiracies, the bloody fighting in the Southern states after 1778 actually diminished the prospect that a mainland counterpart of Toussaint Louverture would rise out of the tobacco plantations.

Nonetheless, as Eugene D. Genovese suggested in his influential study *From Rebellion to Revolution* (1979), the age of revolution, and especially the slave revolt in Saint Domingue in 1791, marked a change in patterns in black resistance. The Caribbean rebels under the leadership of Boukman and Toussaint Louverture sought not only to destroy the power of their Parisian absentee masters but to join the societies in which they lived on equal terms. For black Americans determined to realize the egalitarian promise of the American Revolution, the news from the Caribbean reminded them that if they dared, the end of slavery might be within their reach. Whereas Jemmy and his African recruits hoped only to escape the chains of colonial South Carolina, the slave Gabriel of Virginia, born in the year 1776, wanted to join political society on equal terms. Gabriel and his lieutenants, who instigated the most extensive plot in Virginia history, hoped to force the white patriot elite to live up to its stated ideal: that all men were created free and equal. Leading a small army of slaves in Henrico County, the young blacksmith planned to march into Richmond under a banner emblazoned with the words “Death or Liberty.” He assured one supporter that “poor white people,” who had no more political power than the slaves, “would also join” them in the struggle for equality. Although trial testimony makes little mention of events in Saint Domingue, white authorities like Governor James Monroe harbored no doubts that Toussaint Louverture’s victories had an enormous “effect on all the peoples of colour” in the early national South (Egerton 1993, 169).

In several cases, bondmen who had been carried from revolutionary Saint Domingue by their masters participated in North American slave revolts. In 1792 slaves on Virginia’s eastern shore proposed to “blow up the magazine in Norfolk, and massacre its inhabitants” (Aptheker 1943, 228).

Norfolk County had a white majority, but Northampton and Elizabeth City counties, just across the Chesapeake Bay, had an enslaved majority. Although the rebel leader Caleb, a favored servant and driver, was evidently American-born, several of his recruits were Haitian refugees, and all—according to the trial testimony—had been inspired by the example of Saint Domingue. Two decades later, in 1811, one of the most extensive conspiracies in the history of the United States erupted in southern Louisiana, only a few miles upriver from New Orleans. Slaves led by a mixed-race driver named Charles Deslondes announced their intention of marching on the city “to kill whites” (Aptheker, 249). Although Deslondes, contrary to myth, was not Haitian, many of the roughly two hundred slaves who rose with him had resided in the French Caribbean.

After Gabriel’s execution and the death of twenty-five of his followers in the fall of 1800, slave rebellions on the eastern seaboard became both less common and less politically conscious. Slaves who worked along the rivers in southern Virginia and Halifax County, North Carolina, under the leadership of Sancho, a ferryman, formed a highly decentralized scheme to rise on Easter Monday of 1802. But Sancho, despite having been involved in Gabriel’s plot, shared little of Gabriel’s dream of a multiracial republic. The lack of an ideological dimension appeared even when the dislocation brought on by the War of 1812 and a second British invasion of the Chesapeake once more gave bondmen in Virginia an opportunity to rise for their liberty. Gloucester County authorities jailed ten slaves in March 1813, and the following month found rebels in Lancaster County and Williamsburg “condemned on a charge of conspiracy & insurrection” (Aptheker, 255). By the late summer and early fall, rumors of revolt unnerved inhabitants of Norfolk and Richmond as well.

If the relative ease with which white authorities crushed these isolated rebellions did not extinguish the desire for freedom, it nonetheless reminded leaders in the slave community that the determined white majority in the American South presented insurgents with a formidable obstacle. Denmark Vesey of Charleston, perhaps the most pragmatic of all the rebel leaders, realized that Gabriel’s dream of forcing mainland elites to accommodate blacks’ aspirations to freedom and economic justice was impossible.

Vesey plotted, therefore, not to end slavery in South Carolina, but instead to lead a mass escape from Charleston to the Caribbean, where he had lived and worked as a boy. Hoping to take control of the city on the night of July 14, 1822, Vesey’s recruits—many of them Africans—intended to slaughter the inhabitants of the city and seize bank reserves before fleeing to Haiti, an embattled black republic sorely in need of capital and skilled labor. If Vesey, a prosperous freeman, doomed those who remained behind to renewed repression by
whites, he can scarcely be faulted: He understood that his followers had virtually no hope of bringing down the peculiar institution in South Carolina.

Even Vesey’s unsuccessful exodus, which may be regarded more as mass flight than a revolution, indicated the difficulties of planning an effective strategy amidst large numbers of ever-vigilant whites. Like virtually all rebel leaders in the United States, Vesey recognized the danger of openly recruiting in the countryside. Word of the Charleston plot probably reached several thousand slaves—which is not to say that even half that number committed themselves to the struggle—and there was always a danger that a black Judas would hear the whispers and inform the master class. White authorities had long ago perfected the art of dividing the slave community by offering a tempting reward—freedom—to those who would turn their coats. Like Jemmy and Gabriel before him, Vesey, whose army had more officers than soldiers, planned to rise quickly and present the low country’s black majority with a fait accompli. The victorious armies would not be recruited or armed in advance but raised by the captains as they marched.

Ironically, the bloodiest slave revolt in the United States took place in the decade after Vesey’s failure, at a time when rebellion—as opposed to other forms of resistance—had become virtually suicidal. The slaves in Southampton County, Virginia, who rose with Nat Turner in 1831 shared neither Gabriel’s trust in a second American Revolution nor Vesey’s hope of fleeing to the Caribbean. Although Turner may have expected to establish a maroon colony in the vast Dismal Swamp, his plot gave little evidence of planning or rational preparation. Most likely, the messianic Turner hoped that God would protect and guide his army as the Lord had guided the Israelites. At least fifty-seven whites perished in the revolt, but local militiamen easily routed the ill-equipped rebels; three companies of federal artillery, together with seamen from two warships in the Chesapeake, reached Southampton only three days after the insurrection began.

Although the secession of the Southern states in the winter of 1860–1861 presented militant blacks with precisely the sort of division that rebel leaders typically tried to take advantage of, the Civil War channeled black resistance into patterns acceptable to the politicians of the free states. During the first year of the conflict, as Confederate soldiers repulsed northern invasions, militant slaves across the cotton-growing South saw few options but to pull down the rebel government from within. The plot in Natchez, Mississippi, still shrouded in mystery, stands as but one example of collective resistance during the months before the Confederate debacle at Antietam Creek. Rumors of black resistance spread in New Orleans and Columbia, South Carolina. Seven slaves swung from the gibbet in Charleston in April 1861. The Confederate brigadier general R. F. Floyd urged the governor of Florida to declare martial law in the hope of eradicating a “nest of traitors and lawless negroes” (Aptheker, 301).

Most slaves, however, understood, as Herbert Aptheker suggested in his definitive work on American Negro Slave Revolts (1943), that “the Army of Lincoln was to be the Army of Liberation” (p. 84). Aged slaves with long memories counseled patience and waited for the arrival of Northern forces. Following the Emancipation Proclamation, Northern freemen and Southern runaways, eager and willing to fight, donned blue uniforms in the name of liberty for blacks. Despite the Confederates’ threat to execute black soldiers as slave insurgents, thousands of bondmen fled the countryside, planning to return and liberate their families. By the end of the war, 180,000 African Americans (one out of every five males in the republic) had served in Union forces. Those former slaves who marched back toward the plantations of their birth singing “General Gabriel’s Jig” rightly understood themselves to be a part of the largest slave rebellion in the history of the United States.

SLAVE TRADE

The history of most modern societies has involved, in some form or fashion, the use of coerced labor, including the institution of slavery and the exploitation of slave labor. And where slavery existed—defined as a system in which the production process is carried out by human beings owned by other human beings—a mechanism for supplying slaves was necessary. This mechanism is called the slave trade. While slavery and the slave trade as concepts and as practices have an ancient pedigree and global itineraries, their relationship to the history, practices, and realities of modern societies continues to stir considerable concern and controversy. The tools of historians must be combined with tools and insights from economics, political science, and other social sciences to explore how empirical data and theoretical debates have animated our understanding of the slave trade's global history, especially the transatlantic slave trade.

Slavery was commonplace in many ancient societies, including Greece, Rome, and Egypt. Slaves were forced to work in almost all sectors—agriculture, mining, domestic service, and even as gladiators and soldiers. Many of these slaves were captured in war, but formal mechanisms to supply slaves were also well established. Rome drew its slaves from all over its expanding empire, for example, and at one point there were as many slaves as there were Roman citizens. The slave trade was also a prominent feature of medieval societies, with Africans being enslaved and shipped to the Muslim world across the Sahara, the Red Sea, and the Indian Ocean. Scholars have estimated that as many as 19 million people from sub-Saharan Africa were shipped to the Muslim world between 650 and 1890.

Until the fifteenth century, the major destination for the slave trade was the Muslim world, with slaves coming from Africa and from Europe. In fact, the word slave is derived from the word slav, the name for a large ethnic and linguistic group residing in eastern and southeastern Europe, including Russians, Ukrainians, Poles, Czechs, Slovaks, Bulgarians, and others. In the fifteenth and sixteenth centuries, Africa became the major source of slaves, and the international slave trade was dominated by Portugal, reflecting the development of European colonies in the Americas that needed labor. In the seventeenth century, Britain emerged as the largest carrier of slaves.

THE NUMBERS

There have been three waves of estimates regarding the numbers of Africans who were traded as commodities in the slave trade across the Atlantic Ocean. The first wave included estimates ventured by scholars who repeated earlier numbers gleaned mainly from popular writing and not based on systematic analysis—W. E. B. Du Bois's approximation of 100,000,000 Africans lost to the slave trade was a prime example. Such estimates were the main target of Phillip Curtin's *The Atlantic Slave Trade: A Census* (1969), one of the pioneering studies seeking to provide more accurate numbers. The second wave of estimates, to which Curtin contributed, was based on more extensive compilation and synthesis of available data and estimates using statistical inferences based on population changes in importing countries, but not on research into original sources. Curtin provided an estimate of 9,566,100 Africans between 1451 and 1870, concluding provocatively that it was unlikely that new scholarship would alter his estimate by a number greater than 10 percent. Noel Deerr's *The History of Sugar* (1949–1950) was an earlier representative of this tradition extended but not initiated by Curtin's census. The major impact of Curtin's work was not its originality but its method, comprehensiveness, and timing, appearing at a time when concerns over race and race relations were mounting, and drastically lower estimates of the number of Africans traded were bound to provoke controversy.

Joseph Inikori (1976, 1982) provided one of the earliest critiques of these census efforts. He pointed to his own research and synthesized the work of other scholars as the basis for concluding that Curtin's estimate required a 40 percent upward adjustment. Most important was his discovery of new shipping data that provided more accurate numbers of slaves carried. Beyond confirming that all such estimates are far from complete or final, the continuing debate underscores the centrality of intellectual history in exploring heated disagreements in historical interpretation where perspectives are shaped by the dynamics of color, class, nationality, morality, disciplinary paradigms, ideological orientations, and claims about objectivity.

A third wave is represented by scholars who have compiled the *Trans-Atlantic Slave Trade Database* (TSTD), sponsored by Harvard University’s Du Bois Institute and published in 1999. With data on more than 27,000 slave voyages, TSTD concluded that 11,062,000 Africans were transported from Africa between 1519 and 1867, with 9.6 million landing in the Americas, figures not substantially different from Curtin’s. More than half were carried between 1700 and 1799, and about 30 percent after the abolition of the slave trade by Great Britain and the United States in 1807. Beginning with Prince Henry's traders in 1441, Portugal was the major carrier in the trade involving Africans, and 75 percent of all slaves were carried by the Portuguese in the first 150 years of the trade. Overall, however, British citizens transported 46 percent of all Africans, followed by the Portuguese (29.1%), France (13.2%), Spain (4.8%), the Netherlands (4.7%), and Denmark (1%). Only 2.5 percent of all slaves were transported by slave merchants based in the United States and British
Caribbean. Up until 1820, more Africans were transported across the Atlantic than Europeans—8.4 million Africans to 2.4 million Europeans.

TSTD enables more detailed attention to the geographical distribution of the origins and destinations of enslaved Africans and the resulting demographic and cultural shape of the “diapora” in which Africans were dispersed or scattered. Almost 45 percent of all slaves came from the West African coast that is today Ghana, Togo, Ivory Coast, Burkina Faso, Benin, and parts of Nigeria, for example. As destinations, 41 percent of enslaved Africans were shipped to present-day Brazil, 27 percent to British America, 11 percent to French territories, and 13 percent to Spanish territories. And there was method in the madness, with European slave traders and slave-purchasing areas in the Americas showing preference for Africans from particular regions (e.g., rice-growing South Carolina preferred slaves from Gambia and rice-growing regions of West Africa).

There have also been substantial updates to TSTD, bearing out earlier and unwelcome insistence that all such estimates were only provisional. A new revised TSTD now includes over 34,000 slaving voyages. It recognizes “major gaps” in the 1999 database, especially with regard to the early history of the slave trade and that of Brazil, the largest importing nation. It adds 7,000 new voyages and provides additional information on more than 10,000 voyages in the 1999 database.

POLITICAL ECONOMY
Political economy generally denotes an approach that focuses on the relationship of economic activity—trade and commerce as well as production—and their interrelationships with the activities of government, politics, and the broader society. To paraphrase Adam Smith’s 1776 title for his pioneering volume in this tradition, the slave trade and slavery’s contribution to “the wealth [and poverty of] nations” was critical. This line of thinking was continued in the next century by Karl Marx, who pondered in Vol. 1 of Capital, “the turning of Africa into a warren for the commercial hunting of Black skins” as an initial source for early investment in capitalist production. The approach is also closely related to Walter Rodney’s How Europe Underdeveloped Africa (1974) and similar discussions by such scholars as J. M. Blaut (1992, p. 206) of “the role played by colonialism in industrial production.”

Meeting the need for labor in the Americas was essential if European nations were to realize the goals of mercantilism—favorable trade balance, increased amounts of precious metals, and the like. Therefore, beyond the issue of how many Africans were taken from the continent into slavery in the Americas—especially the horrendous treatment during the middle passage between Africa and the Americas—and who played what role in enslaving them, is the need to understand the contribution of African labor to wealth production in the various nations that were carriers of slaves and beneficiaries from the economic productivity of slave labor.

Expectedly, sharp differences have emerged as well over this area, generally termed “profitability” of the slave trade, an assessment dependent in part on calculations of the number of slaves traded. For example, Roger Anstey (1975) suggested 9.6 percent as the rate of profit in the British slave trade between 1761 and 1897, calculating profits by using data on the number of slaves landed, slave prices, and other data on cost and revenue. Inikori (1976) provided evidence pointing to underestimations in the number of slaves landed in the West Indies and the average price for which slaves were sold. William Darity (1985) used these corrected figures to demonstrate a plausible increase in the rate of profits from 9.6 percent to 30.8 percent, a figure consistent with the conclusion of Eric Williams in Capitalism and Slavery (1944).

Efforts to calculate the contribution of the slave trade to economic development became more controversial when prominent scholars concluded that profits from the slave trade were not large enough to make a significant contribution to British industrialization, a view that diverged from the long-held conventional wisdom about the impact of what had been called “the triangular trade” (Anstey 1975; Engerman 1972; Davis 1984, p. 73). Darity (1990), Barbara Solow (1991), and others highlighted the impact that different definitions, theoretical assumptions and economic models can have in calculating rates of profits, concluding that the slave trade was a relatively important source of industrial capital. Moreover, Ronald Bailey (1986, 1990) has given the term “slave(ry) trade”—activities related both to the slave trade and slavery and closer to the “multiplier effect” concept used by some economists—as the source of profits that should be utilized in calculating contributions to industrialization and not just profits from buying and selling slaves. Substituting profits from the Caribbean trade in place of profits solely from the sale of slaves, he concluded that enough profits could have been generated to finance the British industrial revolution several times over. (As an additional example, the 7,000 new voyages added to the 1999 TSTD database discussed above requires a recalculation of the slave trade’s impact on the expansion of the ship-building and shipping industry.)

In this approach, this contribution from the “slave(ry) trade” would include the important role and economic significance of agricultural crops produced by slave labor in the colonies, including sugar, tobacco, rice, coffee, and cotton, as well as profits generated in related shipping, banking and insurance, and manufacturing, a
central thesis in Williams's *Capitalism and Slavery* and argued by Inikori (2002). Importantly, this approach facilitates a sharper focus on the role of slavery and the slave trade in U.S. history, an emphasis admirably treated, for example, by Du Bois (1896) and in the chapter on “Black Merchandise” in Lorenzo Greene's *The Negro in Colonial New England* (1942).

**MORALITY OF THE SLAVE TRADE**

Ships in the transatlantic slave trade rarely carried Europeans and were rarely owned and operated by Africans. This color/race and class dynamic helps to explain why the controversy over the slave trade provokes sharp debates over morality and ethics. It is so potent because modern capitalist nations, which early prohibited the enslavement of Europeans, were the world's leaders in the enslavement and trade of Africans, a legacy related to both poverty and racism that hovers over world history and the history of many nations and peoples. Even more perplexing, the slave trade and slavery were consolidated and expanded at the same time as the rise of the progressive transatlantic philosophical movement called the Enlightenment in the late eighteenth century, and such practices were enshrined and extended, not abolished, by the American Revolution and the U.S. Constitution. Edmund S. Morgan, a scholar of early America, was provoked to probe the paradoxical marriage of convenience he called “American slavery/American freedom.”

Ideas about abolition surfaced as early as the late 1600s with the work of the Quakers and other religious groups, but it was not until 1807 that legislation to end the slave trade was enacted in Great Britain and in the United States. It was another eighty years before such practices were finally outlawed by all of the nations whose citizens had been involved as slavers and beneficiaries of slavery. Scholarly debates regarding the root causes of abolition and the slow unfolding of its success have been as intense as those regarding the causes and consequences of slavery and the slave trade, with some scholars emphasizing humanitarian motives and others stressing economic and political dynamics. That the system of U.S. slavery that fueled the transatlantic slave trade necessitated for its abolition a civil war resulting in the deaths of more than 620,000 people will guarantee that discussion and debate will continue in the decades to come.

Two hundred years after the 1807 abolition of the slave trade in Great Britain and the implementation of a similar measure in the U.S. Constitution, the slave trade continues to rest uncomfortably in scholarship and in social memory. In recent times, the controversy has taken the form of calls for and debates over apologies for participation in the slave trade and slavery, and over the payment of some form of “reparations” similar to what was provided to Jews and other victims of the Holocaust and to U.S. citizens of Japanese ancestry incarcerated in World War II camps. And there are growing contemporary movements to grapple with new forms of slavery, poverty, and economic coercion in a deepening globalized economy. Research, thinking, and writing about the history of the slave trade should provide a solid foundation for understanding and acting in the present and future.

SLAVE-GUN CYCLE

For the first two centuries of European trade in western Africa (roughly 1441 to 1650), gold was the main product of trade. But as demand for slave labor in the Americas expanded following the phenomenal growth of plantation agriculture and mining from the seventeenth century, European demand in western Africa shifted decisively from gold and other products to captives, leading to the transportation of millions of Africans for enslavement in the Americas between the 1650s and the 1860s. The impact of this trade in captives on African societies has been debated since the late eighteenth century—first, between the abolitionists and the slave traders and, later, among modern historians. One contested issue is the role of the trade in the scale and frequency of wars in western Africa between the 1650s and the 1860s. This is the context for the notion of the slave-gun cycle—that guns were employed in wars that generated captives for export, the proceeds from which were employed to buy more guns to fight more wars that generated more captives. Historians disagree on the quantity of firearms imported during the period and their contribution to the scale and frequency of wars. This entry examines the issue of quantity and the linkages to war. It argues that the linkages presented by both sides of the debate appear to be simplistic. A combination of new evidence and a more complex analysis sheds more light on the subject.

Because of inadequate evidence and the difficulty of interpreting what is available, quantifying various aspects of the transatlantic slave trade is fraught with controversy. An estimate based on a variety of British records—merchants’ private papers, customs records, and parliamentary papers—puts the mean total annual import into western Africa from all regions of the Atlantic basin at between 300,000 and 400,000 guns in the second half of the eighteenth century (Inikori 1977). Other estimates based on more limited archival sources are smaller—190,000 for the 1780s; 140,000 for the 1820s; about 200,000 for the 1860s (Eltis and Jennings 1988).

The debate on the contribution of imported guns to the scale and frequency of wars in western Africa during the era of the transatlantic slave trade has been conducted largely within short time periods with all of western Africa taken as a unit of study. This methodology conceals information that region-specific study covering long time periods reveals. This entry, therefore, takes the major sub-regions of western Africa involved in the transatlantic slave trade, comprised of the Gold Coast (modern southern Ghana), the Bight of Benin (modern Togo, Republic of Benin, and southwest Nigeria), the Bight of Biafra (southeastern Nigeria and southern Cameroon), and West-Central Africa (the area from modern Gabon to modern Angola); discusses changes in the commodity composition of their imports from the early years of their trade with the Europeans; and combines the information with other relevant evidence. The Gold Coast and West-Central Africa began significant trading with the Europeans early in the fifteenth and sixteenth centuries; the Bights of Benin and Biafra came in relatively late during the middle decades of the seventeenth century. For this reason, British records employed in the analysis provide better coverage for the commodities imported into the Bights of Benin and Biafra in the early years.

For the Bight of Benin, cowries (sea shells employed in local trade as all-purpose currency) overwhelmingly dominated the imports in the seventeenth century, being consistently more than one-half of the total value of imports before the last decade of the century. The invoices show no firearms, again, until the last decade of the century. From the latter period, the volume and ratio of imported cowries declined continuously, while that of firearms rose—from approximately 3 percent in 1690/
1692 to 9 percent in 1724. In the Bight of Biafra, copper rods, weighing about one pound each (employed in local trade as all-purpose currency), constituted about two-thirds of the total value of imports in most years between the 1660s and 1680s. In most years from the 1660s to 1690s, there were no firearms at all in the invoices; the ratio of firearms in the invoices for 1661 and 1662 is approximately 7 percent each. Like the Bight of Benin, currency imports declined over the eighteenth century, while firearms increased—from approximately 3 percent in 1701 to 40 percent in 1790. From 1827 to 1839, firearms imported into both regions ranged between 21 percent and 35 percent of total imports, and 14 to 18 percent from 1840 to 1850. During these twenty-four years (with data unavailable for 1844), a total of 1.2 million guns were imported into the two regions from Britain alone, the bulk of which went to Yorubaland, where European traders’ choice of Lagos as their headquarters in the late eighteenth century and the collapse of the Oyo Empire in the early nineteenth century led to almost a hundred years of wars (Inikori 1992).

Detailed study of imports into the Gold Coast and West-Central Africa in the fifteenth and early sixteenth centuries is yet to be conducted. However, a Portuguese gold trade ledger for Elmina (Gold Coast), covering 1529 to 1531, shows that metals (without guns) made up 50 percent of imports and cloth 25 percent; no firearms were imported. From the seventeenth century, firearms flooded into the Gold Coast and West-Central Africa, at a time when the Bights of Benin and Biafra hardly imported any firearms.

When the import data is combined with other evidence, we get a much clearer linkage between imported firearms and wars in western Africa during the transatlantic slave trade era. There is clear evidence showing that local and interregional long-distance trade was expanding in western Africa (the geographical region from Mauritania to Namibia), especially West Africa (the political region from Mauritania to Nigeria), at the time Europeans arrived in the mid-fifteenth century. The early European trade in African products, particularly gold, further stimulated the ongoing trade expansion. Cowries and copper rods were already all-purpose currencies in the pre-European trade. The proportionately large import of these currencies in the early decades of European trade is a reflection of the growing local demand for currency to meet the needs of the expanding local and interregional trade. The low demand for firearms in the early years of European trade shown by the commodity composition is, again, a reflection of the general prevalence of peaceful conditions in the kin-based small-scale polities on the coast and in the hinterland. The minor skirmishes that broke out occasionally between neighbors were brief in duration, and prisoners (if any) were ransomed at the end (Meillassoux 1991, p. 33). For as long as European demand was overwhelmingly dominated by African products, the situation remained largely unchanged.

The massive shift of European demand from products to captives changed everything. As individuals and groups of bandits engaged in kidnapping and raids within polities and across political boundaries in response to growing export demand for captives, the small polities were unable to maintain law and order within, while raids across political boundaries provoked wars between neighbors, wars whose scale and consequences increased considerably. These wars disrupted the preceding interregional trade and shifted demand from currency to firearms. Initially, therefore, the wars were not caused by the import of firearms. The shift of European demand from products to captives was the main cause. However, in due course, the massive import of firearms and their distribution among bandits created conditions that fueled the wars and made them endemic. Because exporting captives provided virtually the only access to firearms, given the nature of European demand, polities in conflict were compelled to sell captives for export, which by itself provoked retaliation and continuation of hostility. On the other hand, the sale of war captives in exchange for firearms made war self-financing, which helped to prolong wars. All these developments were experienced by virtually all the polities in western Africa from Senegambia to Angola at different points in time between 1450 and 1850.

A combination of import data and other evidence thus makes it clear that the slave-gun cycle notion, as often employed in the literature, is simplistic. So, too, is the attempt to distinguish between economic and political causes of war during the Atlantic slave trade period. In the main, the wars were political in nature, but were caused largely by the political complications arising from the actions of individuals and groups of bandits responding to the growing export demand for captives, in the first instance (Inikori 1992, pp. 25–39). Given the small size and the politico-military weakness of the polities on the coast and in the hinterland when the Europeans arrived in the mid-fifteenth century, comparative arguments based on the ratio of imported firearms to population (Eltis and Jennings 1988) are not well-founded. Also erroneous is the argument that Europeans and their firearms made no difference to the wars of the slave trade era because before the arrival of Europeans political leaders in western Africa were regularly engaged in wars for the accumulation of slaves as a form of wealth owing to land laws that prevented private accumulation of land and capital as wealth (Thornton 1992). Linguistic and other evidence from West-Central Africa (Hilton 1985; Vansina 1989) and archival and oral evidence from other regions show that the largely kin-based polities on the coast and in the hinterland, and even the Kongo kingdom in West-Central Africa, were not engaged in slave gathering wars in the fifteenth century,
and they had no accumulated slaves for domestic use or for sale when the Europeans arrived. A few captives were being exported across the Sahara at the time, but that trade was centered in the interior savanna; most coastal polities and their hinterlands were not involved. What is more, the evidence shows unambiguously that there were no legal barriers to the private investment of capital in land and agriculture when market conditions were appropriate. Finally, wars continued in western Africa for some decades after the abolition of the transatlantic slave trade in the mid-nineteenth century because the conditions for sociopolitical conflict created by the export demand for captives continued to exist even after abolition.

**SLAVEOWNERS**

**SEE** Slavery.

**SLAVERY**

It has been common for many generations to begin essays on American slavery by noting how commonplace slavery is: It is sanctioned in the Old Testament and has appeared in some form throughout recorded human history, from ancient Egypt to the capture and enslavement of European Christians by Muslims in the Middle Ages to the present. Writers also commonly note that slavery existed in Africa, that Africans sold other Africans into slavery, and—though this is a relatively recent addition to the "stock" essay—that western Europeans ended slavery in a relatively short compass, from about the time of the American Revolution, when northern states began to adopt abolition statutes, through the 1860s.

All of this is true. However, the emphasis has important political implications. For that picture of slavery makes it look natural. It employs the "everybody does it" argument to demystify a practice of immense horror. In fact, those arguments were employed with great facility by proslavery thinkers to justify the continuation of the institution. During debates over the Fugitive Slave Act, Senator John Bell of Kentucky said that slavery has been "contributing in a hundred various forms and modes, through a period of thousands of years, to the amelioration of the condition of mankind generally, though sometimes abused and perverted, as all human institutions, even those of religion, are" (U.S. Congress 1850, 1105).

Senator Bell (who ran unsuccessfully for president of the United States in 1860) found that slavery was "still contributing to advance the cause of civilization through, if you please, having its origins in individual cupidity, still mysteriously working out a general good" (U.S. Congress 1850, 1105). He went so far as to reason from there that slavery was not inconsistent with God's law.

Moreover, saying that every society engaged in slavery is misleading. The nature of African American slavery was different in kind from slavery in many other societies. This is frequently lost on those who seek to make African American slavery look commonplace and thus minimize the nature of the harm. Grecian and Roman slavery was nonracial and temporary, for example. The children of people enslaved in one generation might rise to the ranks of free people, and slaves were incorporated into the society more generally.

It is now becoming more common to emphasize other parts of the institution of slavery that resulted in the forced migration of 11 million people to America, nearly one-half million of whom came to English-speaking...
North America from the seventeenth through the mid-nineteenth centuries. (The importation of slaves into the United States was outlawed in 1808, although some people were imported illegally after that.) The institution built on centuries of European experience with slavery. Slavery survived in parts of Spain through the 1500s; soon slavery spread to Spain's colonies in America. In fact, in 1495 Columbus brought 500 Native American slaves back to Spain. But there were important differences. The slavery that developed in the Americas was brutally violent and perpetual. Slaves were often isolated from free people and left with no hope of having even their children escape from slavery.

The institution was revived and expanded in light of extraordinary needs for labor. Violence permeated it, including the forced separation of families, wars of conquest in Africa encouraged by the European market for humans, the middle passage to America, and brutalization on plantations in America.

**ORIGINS**

Many historians debate the origins of slavery: in European practices such as slavery in Spain in the 1400s, in a legal tradition that stretched back to Roman law, in cultural patterns that encompassed slavery in the Old Testament, in economic needs, and in race prejudices. The legal traditions came largely from Spain—and through Spanish law, from Roman law. European-imposed slavery came ashore in the West Indies in the late 1400s and early 1500s, then spread from the Caribbean to the mainland. Historians have spent much time trying to discern how and when slavery came to British North America. The first black people brought to Virginia in the 1620s seem to have had a status similar to that of indentured servitude, where they worked for a limited period of time and then became free. But by the 1660s, it appears that a system of inherited slavery had emerged in Virginia and elsewhere in mainland British North America. Children's status followed that of their mothers, so the offspring of slave mothers were also slaves. The best answer as to why appears to be that a combination of economic interests, racism, and cultural practices created the American slave system. And while race lies at the center of the institution of slavery, not all blacks were slaves. No whites were slaves, either.

And yet the human spirit longed to be free, even as the system of slavery grew in British North America and statutory laws grew up around it. In 1739 the Stono Rebellion took place along the coast of South Carolina. Something like sixty slaves began the rebellion by stealing weapons along the Stono River. In the wake of the rebellion, the statutory law of South Carolina became harsher and working conditions deteriorated. Shortly afterward, in 1741, there was an alleged plot by slaves in New York City, where 10 percent of the population was enslaved. The extent of the plot remains in dispute, but more than two dozen slaves were executed in the aftermath.

**SLAVERY AND AMERICAN REVOLUTION**

Even as the slave population and the importance of slavery as a labor system were increasing, many in British North America began thinking in the Enlightenment's terms of a universal right to freedom. American revolutionists gave consideration to the terms of slavery. In a draft of the Declaration of Independence, Thomas Jefferson included the slave trade as one of the offenses of the English Crown, but that indictment was subsequently removed. Like the delegates to the Continental Congress, Americans at the time of the Revolution were more generally unwilling to act on antislavery values. One of the great paradoxes of American history is the question of how Americans could fight a war based on the idea of freedom while still maintaining slavery. Or, in the words of Dr. Samuel Johnson, "How is it that we hear the loudest yelps for liberty among the drivers of negroes?"

There was, then, in the ideology of republicanism popular in early America—that conjunction of faith in widely spread property holdings, independence from economic dependency, and political independence as well—a strange relationship with slavery. Harriet Beecher Stowe drew out the contradiction in her 1852 novel *Uncle Tom's Cabin* when a boy beat his slave. The boy's uncle asked whether that was consistent with the republican principle that "men are born free and equal." The boy's father said that the phrase was [one of Tom Jefferson's pieces of French sentiment and humbug. It's perfectly ridiculous to have that going the rounds among us, to this day.… we can see plainly enough that all men are not born free, nor born equal; they are born anything else. For my part, I think half this republican talk sheer humbug. It is the educated, the intelligent, the wealthy, the refined, who ought to have equal rights and not the canaille. (Stowe 1852, p. 74)

Such an exchange pointed out one of the abolitionists' arguments: that slaveholders cared little for the equality of anyone, white or black. Some abolitionists argued, instead, that the slavery of Africans was but a step on the way to further inequality.

Historian Edmund Morgan's 1975 book, *American Slavery, American Freedom*, takes up the paradox of Americans' claims for freedom in the Revolution and their concomitant respect for slavery. His answer is that slavery
provided the social and intellectual setting for whites’ freedom. In essence, slaves made it economically possible for white men to have democracy. Moreover, the presence of slavery alerted white men to how awful servitude might be—and thus led them to be vigilant in the protection of their rights. This draws in some ways from the insight of South Carolina senator James Henry Hammond, who spoke in 1858 about slaves as the “mudsill class” who made white freedom and equality possible. Though Hammond turned to this argument as a basis for continuing slavery, later historians have used his theory for insight into the nature of political ideology and slavery. In essence, they looked to Hammond to decode why slavery, so inconsistent with the American language of freedom, had such a powerful hold on the minds of white men.

**POSTREVOLUTIONARY CHANGES**

In the aftermath of the American Revolution, the institution of slavery grew in popularity in the United States, even as the movement opposing slavery also grew. In the northern states, gradual abolition plans began the process of ending slavery. For example, Massachusetts and Pennsylvania passed statutes that would emancipate slaves born afterward, following a period of apprenticeship. The statutes also freed slaves brought into the states. Thus, by about the middle of the nineteenth century, no more slaves would live in those states; those who were enslaved prior to the enactments would have died, and the others would have been freed. One effect of this was to encourage owners to sell their slaves to southern states, where they and their children would continue to be slaves.

The Enlightenment continued to have some adherents. Thomas Jefferson noted in 1784 in his *Notes on the State of Virginia* that “The whole commerce between master and slave is a perpetual exercise of ... the most unremitting despotism on the one part, and degrading submission on the other. ... I tremble for my country when I reflect that God is just; that His justice cannot sleep forever” (Jefferson 1984, pp. 288–289). Events elsewhere also contributed to the debate over slavery. In Haiti, Enlightenment ideas and the human impulses to resist slavery led to a revolution among the half-million slaves in 1791, which resulted by 1803 in the end of slavery in Haiti. The free black state was close to alone in the world; the United States would not receive an ambassador from Haiti or even recognize Haiti. The revolution included extraordinary violence. Hundreds of whites died; some white refugees fled from Haiti to South Carolina, where they provided living reminders of what might happen in a slave society. The United Kingdom ended slavery in its colonies in 1833, at a great financial cost, following decades of abolitionist agitation.

**CAPITALISM AND ANTISLAVERY SENTIMENTS**

There remains substantial question about the origins of antislavery sentiments. They grew in conjunction with the development of the market economy, which has led some historians to ask, “What is the relationship between capitalism and abolitionism?” One might think at first that there is some tension, in that the institution of slavery seems to have been a fairly effective way of obtaining (relatively) inexpensive labor. Anyone wondering about how important slavery was in the development of the southern agricultural economy might perform a simple experiment: Spend an afternoon—just an afternoon—working in a field in Alabama in July. Then ask, would anyone perform this kind of labor unless forced to do so?

However, the market economy seems to have had a positive effect on antislavery sentiments; in part it made people aware of their fellow humans, in part it led to competition with free labor. Thus, free laborers had both sentimental and economic reasons for opposing slavery. That did not necessarily mean that white voters always welcomed the idea of recently freed slaves living in their community; but for reasons of self-interest, they often had a desire to end slavery. In these cases, the economic interests of many voters merged with the humanitarian sentiments of others to give strength to the antislavery cause, even as proponents of property rights in the South clung tightly to the institution.

One might also consider that Adam Smith was the author of an important treatise, *Theory of Moral Sentiments*, as well as *The Wealth of Nations*. As the market economy led the way for the development of middle-class sentiments that recognized the need for promotion of humanity (Harriet Beecher Stowe’s *Uncle Tom’s Cabin* is a prominent example here), it also led the way for economic competition by free workers with slavery. The Republican Party’s slogan in the 1850s, for example, was “Free Soil, Free Labor, Free Men.”

W. E. B. Du Bois discussed this in his 1935 book *Black Reconstruction*, one of the most important works ever written on slavery and its aftermath. The book was an important corrective to the then-dominant school of historical scholarship that relegated slavery to the sidelines in the discussion of the Civil War and that decried the domination of the South by corrupt and lawless Yankees and blacks during Reconstruction. Du Bois dealt with the differing meanings of slavery for white workers—the impact of slave labor on driving down wages, as well as the presence of free black workers in driving down wages. Du Bois wrote, for example, that white immigrants “blamed blacks for the cheap price of labor. The result was race war; riots took place which were at first simply the flaming hostility of groups of laborers fighting for bread and butter” (Du
Bois 1935, p. 18). Du Bois pointed out the complex relationship between white workers and slaves and free blacks, which made it sometimes difficult to tell how voters would define and express their preferences.

**GROWING TENSIONS OVER SLAVERY AND ANTISLAVERY**

In the United States there was other action. Congress outlawed the importation of slaves from outside the United States in 1808 (the earliest date permitted under the Constitution). That had the effect of increasing the prices of enslaved people and also encouraging better treatment because of their increased value. The controversy over the extension of slavery to newly acquired territories continued as well. The Northwest Ordinance of 1789 had prohibited slavery in the Northwest Territory (including Ohio and Michigan), which Virginia had ceded to the United States. Southern states worried that if free states were admitted, the South would gradually lose political power. In 1820, Congress passed the Missouri Compromise, which prohibited slavery in territories north of Missouri’s southern border. For a while that contained discord over slavery. Thomas Jefferson wrote—with great foresight—about the compromise that “this momentous question, like a fire bell in the night, awakened and filled me with terror. I considered it at once as the knell of the Union.” He predicted that although sectional divisions over slavery were quelled for the time being, “a geographical line, coinciding with a marked principle, moral and political, once conceived and held up to the angry passions of men, will never be obliterated; and every new irritation will mark it deeper and deeper” (Ford 1904–1905, vol. 12, pp. 158–160).

Subsequent events proved Jefferson correct. By the early 1830s, the politics of slavery grew more divisive. Nat Turner’s August 1831 rebellion in southern Virginia led to the deaths of at least fifty-five white people—and to a serious debate in the Virginia legislature about a gradual abolition plan. The plan failed, narrowly; in other southern states, there was growing reluctance even to discuss the possibility of termination of slavery. In 1835, when abolitionists attempted to use the U.S. mail to deliver abolitionist literature, southern states further closed ranks. After 1835, there was little serious antislavery talk in the South; the nation was on a course toward Civil War and then, emancipation.

After 1835, southern congressmen imposed the “gag rule,” which prohibited discussion of the abolition of slavery (or even the receipt of abolitionist petitions) in Congress. Southerners seem to have made an already degrading slavery harsher as well, for instance, by taking seriously statutes prohibiting the teaching of slaves how to read and by generally policing slaves more closely than they had before. Moreover, in the nineteenth century southern states moved to make emancipation of slaves harder and in some cases to require them to leave the states shortly after receiving freedom. College professors in southern institutions wrote important proslavery tracts, including Thomas R. Dew of William and Mary, Albert Taylor Bledsoe of the University of Virginia, R. H. Rivers of Alabama Wesleyan College (now the University of North Alabama), and William Smith of Randolph Macon College. Staples of the proslavery argument were that slavery was ubiquitous in history and that slave societies profited greatly from the institution. They concluded that slavery was not a drag on society but a principle cause of civilization. Moreover, they argued that economic and social stability required slavery. They pointed to Haiti and suggested the dangers to white society from the abolition of slavery.

In 1850, Congress again passed a comprehensive compromise (known as the “Compromise of 1850”) that, among other things, required northern states to assist in the return of fugitive slaves. But that could not settle the issue for long. The Supreme Court invalidated the Missouri Compromise in 1857 in the *Dred Scott* case, as it attempted to install southern constitutional thinking on slavery as the law of the land. In 1860, Abraham Lincoln won election, and shortly thereafter South Carolina, fearing for the future viability of slavery, seceded. Other southern states followed and the Civil War began in 1861. During the secession discussions, southern politicians frequently spoke about the importance of preservation of slavery, and some advocated the reopening of the slave trade.

**DIFFERENCES OF SPANISH AND FRENCH AMERICAS**

Slavery was present in Spanish and French America, as well as in English-speaking America. In Spanish and French America, unlike English-speaking America, there seems to have been intermarriage between owners and slaves, and slaves seem to have had more formal legal protection. That has led to much discussion of whether the slave systems of Spanish and French America were more benign than in English-speaking America. There was, as many have pointed out, extraordinary violence in the slave systems throughout the Americas. After the Civil War finally ended slavery throughout the nation in 1865, slavery continued for a few more years in other parts of the Americas. Brazil finally ended slavery in 1888, which marked its termination in the Americas.

SLAVERY HYPERTENSION HYPOTHESIS

Early in the twentieth century, before chronic high blood pressure (hypertension) was even recognized as a serious medical condition, colonial physicians in Africa had already developed an interest in the apparent absence of hypertension among indigenous black populations. Rather than interpreting these observations as some sort of natural advantage possessed by Africans, they attributed the difference to a carefree traditional life, uncomplicated by the stresses of industrialized society. In the United States, on the other hand, evidence emerged by the 1930s that black Americans had a higher prevalence of hypertension than whites, and this observation spawned many theories about anatomic and physiologic differences that might explain the disparity.

Despite extensive research since the mid-twentieth century on social and behavioral factors that contribute to hypertension, there has been a persistent impulse in American biomedicine to view racial groups as representing human subspecies. Explanations for racial health disparities therefore tend to be couched reflexively in terms of hypothesized genetic factors. This tradition of racial essentialism led to a surfet of ad hoc hypotheses about hypertension, such as relating blood pressure levels directly to skin pigmentation or to excess testosterone levels in black men. Some authors suggested that because blacks originated from hot and humid environments, they possessed innate capacities for sodium retention that proved maladaptive in other settings. Others proposed that salt supplies for the sub-Saharan progenitors of African Americans were historically limited.

A POPULAR HYPOTHESIS

One of the most widely disseminated of these “just so” stories is the “slavery hypertension hypothesis,” an evolutionary theory that relates excess hypertension risk in New World blacks to natural selection during the “Middle Passage” for the trait of retaining sodium. The theory was posited at least as early as 1983, and it was adopted in the late 1980s by the hypertension researcher Clarence Grim, who has championed the idea energetically in the subsequent decades. Grim speculated that sodium loss from sweating, diarrheal stools, and vomit during the transatlantic voyage led to high levels of mortality from dehydration, and therefore to selection pressure against genes coding for greater sodium excretion in the kidneys.

As this hypothesis grew in popularity, some researchers began to voice skepticism, arguing against the theory on the basis of population genetics, details of the physiology of hypertension, and basic evolutionary biology. For example, Philip Curtin, a historian of the slave trade on whose work Grim had drawn heavily, denied any historical validity to the proposition that Africa had traditionally been “salt-scarse.” Curtin asserted that his own work had been misquoted on this point. He also disputed the mortality estimates cited by Grim, noting that these figures were not only incorrect or outdated, but that they
were referenced so poorly that their original source could not be identified. Curtin argued that Grim’s proposition that a majority of deaths were due to diarrheal disease was equally baseless, and he concluded that Grim’s hypothesis not only lacked supporting evidence, but that what little evidence did exist directly contradicted the theory.

Grim has largely avoided responding to specific criticisms, and in response to these arguments he countered vaguely that Curtin had “failed to grasp several key physiological and epidemiological principles underlying the hypothesis.” Other defenders of the hypothesis have been similarly oblique in print. The editor of the journal *Psychosomatic Medicine*, for example, dismissed critics of the Slavery Hypothesis as “left-thinking” people, admonishing them that race and ethnicity are “too important to be ignored or politicized” (Dimsdale 2001, p. 325).

**THE SLAVERY HYPOTHESIS TODAY**

The slavery hypertension hypothesis remains widely accepted, as evidenced by the numerous hypertension textbooks that describe the theory in detail, often without mention of any criticism. The hypothesis is frequently invoked in the medical literature to justify the more general proposition of innate biologic difference in cardiovascular disease risk and treatment efficacy. For example, the editor of the *American Journal of Cardiology* wrote in 2001 that “[i]t is this selective survival among the descendants of surviving slaves of genes responsible for an increased ability to hold on to salt that is now responsible for the exceptionally high prevalence of hypertension in African-Americans” (Roberts 2001, p. 1344).

The theory also reappears periodically in the popular press. In a 2005 feature about the Harvard economist Roland Fryer Jr. for example, the *New York Times Magazine* depicted the slavery hypothesis as a new and exciting idea from the young academic superstar. “Fryer’s notion that there might be a genetic predisposition at work was heightened when he came across a period illustration that seemed to show a slave trader in Africa licking the face of a prospective slave,” wrote the profile’s author, Stephen Dubner. He continued, “a person with a higher capacity for salt retention might also retain more water and thus increase his chance of surviving. So it may have been that a slave trader would try to select, with a lick to the cheek, the ‘saltier’ Africans. Whether selected by the slavers or by nature, the Africans who did manage to survive the voyage—and who then formed the gene pool of modern African-Americans—may have been disproportionately marked by hypertension” (Dubner 2005, p. 56).

In this instance, the reasoning happens to be exactly backwards, as the “saltier” Africans would be exactly the ones who were not retaining sodium. Disregarding this logical error, what is remarkable is the perpetual recurrence of the theory as so new and exciting that no actual data (e.g., a measurement of a genetic marker for sodium metabolism) is required. The single piece of “evidence” cited in this account is a 1764 antislavery engraving, the interpretation of which as a depiction of tasting for salt is dubious at best.

**BEYOND THE SLAVERY HYPERTENSION HYPOTHESIS**

In the case of the slavery hypothesis, a vague suggestion has achieved considerable scientific and popular dissemination, despite a dearth of evidence and denunciations by many critics that have generally gone unanswered. Respected researchers cite the theory readily, in many cases even expressing their aesthetic attraction to the idea. This is echoed in the popular press, where writers have further exaggerated the simplistic genetic determinism and essential black abnormality that are implicit in the hypothesis. Racial groups have been portrayed as fundamentally distinct in physiology, conforming to the stark distinctions that are common in the social sphere. Moreover, the casual acceptance of this outright speculation has become an edifice upon which to construct further elaborations, such as race-specific therapies, and the many facets of this mythology have come to reinforce each other and create the impression of evidence, when in fact there is little or no evidence at all.

**SLAVERY INDUSTRY**

The word *industry* (from the Latin *industria*, meaning “diligent activity directed to some purpose”) generally refers to a combination of business operations related to a...
primary economic product or process. Hence, slavery industry refers to business activity related to the institution of slavery, including not just the process of supplying slaves but also the relationship of slavery-related activity to linked activity in manufacturing, agricultural production, commerce, shipping, and financial institutions. The main issue involves exploring whether Africa, the slave trade, and slavery-related economic activity—conventionally characterized as the triangular trade or what Ronald Bailey (1992) calls the slave(ry) trade—was important to the development of commerce and industry in Europe, especially Great Britain, and the United States.

An estimate of the numbers of Africans taken as slaves was produced by Harvard University's Transatlantic Slave Trade Database in 1999. It provided up to 226 pieces of information for more than 27,233 slaving voyages. Some 11,062,000 Africans were transported between 1519 and 1867, though these numbers are constantly revised upward. About 55 percent were transported between 1700 and 1799, and 29.5 percent between 1800 and 1849. Surprisingly, about 30 percent were transported after Britain's slave trade abolition acts of 1807.

British slave traders (including those living in British colonies) carried almost 46 percent of all slaves, and the Portuguese were responsible for about 29.1 percent. The remaining Africans were carried by France (13.2%), Spain (4.8%), the Netherlands (4.7%), and the United States (2.5%). British slave traders dominated in the all-important period in the eighteenth century when European industrialization surged. Some 280,000—about 2.5 percent of all slaves—were imported into the United States, and 48 percent of these were imported after the beginning of the American Revolution (1775–1783).

Some scholars have called the forced importation of Africans into the New World cauldron before the nineteenth century "the Africanization of the Americas," one of the most significant demographic transformations in world history. Up to 1820, Africans outnumbered Europeans by a ratio of over 3 to 1 among those people who were transported across the Atlantic: almost 8.4 million Africans and 2.4 million Europeans. This had an obvious impact on population trends in Africa (depopulation) and in the Americas. The black population of the West Indies, for example, grew from 15,000 to 434,000 between 1650 and 1770—an increase of almost 2,793 percent—while the white population remained almost static, increasing from 44,000 to 45,000. The need to "repeople" the Americas resulted in part from the demand for labor and the almost genocidal impact that European settlement had on the Native American population. Thus, African peoples composed an even larger proportion of the labor force in all of the American regions associated with expanded Atlantic commerce than is generally known.

Beyond the number of Africans who were enslaved, the most hotly debated issue has been the impact that enslaved African labor had on the economic development of slave-trading nations. This was the central thesis in a book by Eric Williams (1911–1981), historian and former prime minister of Trinidad and Tobago, titled Capitalism and Slavery (1944). Williams's book is, in his words, "strictly an economic study of the role of Negro slavery and the slave trade in providing the capital which financed the Industrial Revolution in England and of mature industrial capitalism in destroying the slave system" (1944, p. v). Both aspects of his argument continue to provoke considerable debate, especially whether or not British abolition resulted more from economic forces than from humanitarian impulses. This issue has particular relevance to the late eighteenth and early nineteenth centuries, when large-scale manufacturing using machines became the dominant activity in industrial capitalist economies, especially in Great Britain and the United States, with cotton textiles as the leading sector.

For example, British colonies in the Caribbean and in the South, where slavery thrived, produced an average of more than 80 percent of the total value of British America's exports in the seventeenth, eighteenth, and nineteenth centuries. Enslaved African labor played a central role in the production of rice, sugar, tobacco, and cotton and in other key sectors, including the mining of gold, silver, and precious metals. Sugar and cotton, however, are the two most important sectors, and data in Joseph Inikori (2002, p. 489) bear this out: from 1752 to 1754, sugar's share of British American imports into Britain was 49 percent as compared to cotton's 2 percent. By 1814 to 1816, sugar's share was 52 percent and cotton's only 22 percent. By the 1854–1856 period, however, cotton dominated with 48 percent as compared to sugar's 15 percent.

Sugar and its cultivation provide the first context and a key link in the story of the evolution of racial slavery in the Americas, a point early recognized by Noel Deerr, who concluded that trying "to write a history of sugar without at the same time treating of slavery was like trying to produce Hamlet with the part of Laertes omitted" (1949–1950). Sugar was the crop for which large-scale plantation slavery was constructed, first on European islands in the Atlantic and then in the Caribbean. It was brought over to Hispaniola (now Haiti) in 1493 by Christopher Columbus (1451–1506), who had learned about its cultivation from his Italian father-in-law on Madeira Island, a Portuguese territory. Once transferred to the so-called New World, sugar production became a crucible with an incessant demand for labor of any type—first Native American and then European indentured servants, before the industry fastened onto African labor that was more accessible, available, abundant, and cheap. Scholars have estimated that between 60 and 70 percent...
of all the Africans who survived the transatlantic slave trade ended up as slaves on the sugar plantations of the Americas.

Cotton was the most decisive raw material for the British and U.S. industrial revolution in textiles, the leading industrializing sector in both nations. The industry was spurred by the invention and improvement of such technologies as the flying shuttle (1733), the spinning jenny (1764), the mule (1779), and the power loom (1785). But the labor of enslaved Africans was also crucial. In 1860 enslaved Africans working on only 3 percent of the earth’s land mass in the South produced 2.3 billion pounds of cotton, or 66 percent of the world’s total crop, up from 160 million pounds in 1820. This was the sole source for 88.5 percent of British cotton imports in 1860, and even supplied the growing needs of a rapidly expanding cotton textile industry centered in New England after 1790. African and slave-based economies in the Caribbean also provided important markets for British and later American manufactured cloth. Moreover, economist Robert North and others concluded that incomes from marketing slave-produced cotton, tobacco, rice, and sugar—products “sold in the markets of the world”—shaped the pattern of regional specialization and the division of labor that helped to consolidate the U.S. national economy before the Civil War (1861–1865).

Beyond its pivotal contribution to consolidating the first global commercial and industrial economies centered around the Atlantic Ocean, the “slave(ry) trade” was also a focal point of intense national rivalries among European powers. Such rivalries were part and parcel of the rise of new nation-states, initial “testbeds” in which the policies and techniques associated with mercantilism, international diplomacy, colonial administration, and war were refined.

Many historical aspects of the slavery industry involving people of African descent from the fifteenth century to the nineteenth century continue to have contemporary consequences. Slavery and the slave trade helped shape the persisting inequities that have historically existed in the economic and social conditions of peoples of African descent all over the world, a theme provocatively captured in the title of Walter Rodney’s How Europe Underdeveloped Africa (1972). Second, the slavery industry played a key role in fostering and sustaining racism, an ideology that groups human beings into socially constructed biological categories labeled races, and then treats these groups as if they are inherently “inferior” or “superior” in the allocation of economic, political, and social resources and opportunities.

Inequality based on class and race has historically been the target of social protests from the earliest days of the slavery industry and continuing through the civil rights and Black Power movements up to the present. Recent calls for reparations—which demand apologies and various forms of compensation to “repay” people of African descent for their contribution to the profits and developmental success of nations, companies, and citizens with historical ties to the slave trade and slavery—have sparked considerable controversy. Some governmental units have demanded full disclosure of corporate ties to the slave trade and slavery as a precondition for granting contracts. Other recent movements, however, do not distinguish between historical forms and consequences of slavery and the slave trade that linked African peoples to the rise of capitalism from more recent systems of exploitation and oppression, such as the growing international traffic in human beings associated with contemporary globalization. Such continuing debate and ongoing struggles will undoubtedly shape these movements for social change for many decades to come.

SLEEPER EFFECTS
People receive hundreds of persuasive messages on a given day. Naturally, they discount a great majority of these messages by relying on cues such as the credibility of the message source. In general, it is expected that noncredible sources present invalid arguments. Therefore, communications associated with noncredible sources generally do not bring about substantial attitude change in response, and may be regarded as ineffective influence attempts. Decades of research on the sleeper effect, however, suggests that it would be misleading to reach that conclusion without measuring attitudes down the line again. People are not very good at remembering the original context of everything that they learn, and as a result, it is possible that they may continue to remember the message well but have a hard time remembering its source. Thus, forgetting the noncredible source of the message or simply dissociating it from the message may bring about a delayed increase in persuasion. This possibility, known as the sleeper effect, is counterintuitive because the impact of a persuasive message is usually greater at the time of exposure than some time after exposure.

As a data pattern, the sleeper effect was identified in the early 1930s. However, systematic study of the effect and its mechanisms started much later, in the 1950s (e.g., Hovland and Weiss 1951). During World War II Carl Hovland and colleagues were interested in evaluating the impact of propaganda films commissioned by the army on the morale and opinions of enlisted U.S. soldiers. In one of their studies (Hovland, Lumsdaine, and Sheffield 1949), soldiers watched a film from the Why We Fight series and reported their opinions either five days or nine weeks after exposure to the film. Measures of opinions taken five days after the presentation of the film suggested that the film did not have an impact on the opinions of the soldiers. When measured again nine weeks after exposure, however, the researchers found that the opinions of those who had watched the film shifted in the direction of advocacy, whereas the opinions of those who had not watched the film remained unchanged. Thus, the film had an effect, but it required some time to surface. The term sleeper effect was coined after this observation.

Several mechanisms have been considered to account for the effect. However, variants of the discounting cue explanation have been especially popular (for a review of primary explanations, see Kumkale and Albarracin 2004; see also Pratkanis, Greenwald, Leippe, and Baumgardner 1988). According to this theory, a noncredible message source induces suspicions of invalidity and temporarily decreases the impact of an otherwise persuasive message; consequently, little or no persuasion takes place at the time of exposure. Over time, though, the attitudes of the recipients shift in the direction of advocacy, either because the recipients forget the discounting information (forgetting hypothesis) or because they do not spontaneously associate the discounting cue with the message any longer (dissociation hypothesis). When they identified the sleeper effect for the first time, Hovland and colleagues (1949) suggested that the recipients might have forgotten the noncredible source of the message but remembered the message itself. In a follow-up study Hovland and Weiss (1951) found evidence for the sleeper effect again, but measures of recall for the message source suggested that the recipients could still remember the source of the message. Based on this finding, Hovland and colleagues proposed that forgetting the discounting cue was not necessary for the sleeper effect to take place; a weakened association between the message and the discounting cue could generate the effect as well. To the extent that the discounting cue becomes less accessible than the message over time, the likelihood of observing the sleeper effect should increase significantly. For several decades researchers concurred that the sleeper effect could be guided by either of these processes. Despite widespread acceptance of these earlier findings, subsequent research revealed that the effect might not be as strong or reliable as once thought. A recent synthesis of the relevant literature, however, revealed that the sleeper effect takes place reliably under certain circumstances, such as when the recipients deeply think about the communications at the time of receiving the communications (Kumkale and Albarracin 2004). At the very least, this synthesis verified that there is evidence for the sleeper effect in persuasion.

G. Tarcan Kumkale
SLUMS

Slums are squalid sections of a city or town, areas in which most inhabitants are in or near poverty, stores and residences are cheap and dilapidated, and streets are narrow and blighted. Slums have been created in various locations; where they arise depends upon political and economic conditions in a community. In early industrial cities of England and the United States, slums housed the lowest paid workers not far from the center of the city, close to factories gates. To this day, slums in English and U.S. cities are typically located in these areas, though often the factories have closed down. In other cities, where central areas retained high land and rent value, large public housing projects were built on the outskirts and slums developed and still exist on peripheral areas (e.g., Paris). Perhaps the world’s largest slum (Dharavi) is on the northern edge of the city of Mumbai (formerly Bombay). In Mexico City and other cities of Latin America, Africa, and Asia, slums exist both near the heart of the city and on the outskirts. The latter are impoverished shanty settlements created and inhabited by squatters, many of whom are relatively recent migrants.

SLUM CONDITIONS AND CAUSES

Slums are usually the most stigmatized parts of a city or town (other areas carrying high social stigma, such as skid rows, red-light districts, and docks, often are located near slum neighborhoods). In the mind of the general public, the disrepute and stigma of the slum area washes onto the people who frequent or inhabit it. When most people think of a slum they think of residents who deviate from the morals, norms, and standards of public decency held up by the wider conventional community (i.e., people involved in serious crime, drug and alcohol abuse, juvenile delinquency, gang violence). People also frequently invoke the concept of “social disorganization” to describe the slum; in other words, they see it as an area lacking the sociocultural institutions, order, coherence, and predictability found in more economically stable environments.

Sociologists and anthropologists, however, paint a more nuanced picture of slum life. Research shows that a broad range of individuals and households live in slums, from the “routine-seekers” and “decent” residents, who abide by the norms and values of the larger society, to the “action-seekers” and “street” folk, who are more likely to flout or reject those standards (Gans 1962; Anderson 1999). Additionally, research on slums often highlights the ways in which ongoing life is organized rather than disorganized. Communication channels, interpersonal obligations, status symbols, local institutions, and public etiquette usually do exist in a slum, although these may be quite different from those of middle-class neighborhoods in a city or suburb. As the literature on local community organizing in slum areas shows, outsiders often are surprised at how much potential or actual organization exists (e.g., in the form of leadership and engagement in local social networks) even in allegedly disorganized poor neighborhoods. Having said this, one must not romanticize slums as bastions of salt-of-the-earth authenticity; all too often life in them is short and brutal, with miserable living conditions and wasted human potential.

It is tempting to think that slums are an urban anomaly produced only when something goes terribly wrong in a city. However, the high prevalence of slums and the ease with which they grow suggests that their causes lie in conventional and institutionalized routines of business as usual. Urban space is stratified as the most powerful people or those with the greatest wealth occupy the most desirable parcels of land. In cities where land and housing are commodities, the most desirable land is expensive, and the worst locations (e.g., noisy, wet, polluted) are cheap. Early slums developed when people built crowded substandard housing on the cheapest land and rented it to poor households with earnings too low to allow them to live in better but more costly areas. Beyond that simple process, the creation of slums involves more subtle causes of concentrated poverty and property decline.

By definition, cities and towns that have in their neighborhoods a mixture of housing types and the full price range in housing, from cheapest to most expensive, are places that do not have highly concentrated poverty, since the poor can live dispersed in fairly close proximity to the nonpoor. Also by definition, places where only the affluent reside are places that have no concentrated poverty in them; although, by excluding the poor, such places may contribute to the concentration of poverty in other locales. For concentrated poverty to occur, the nonpoor must have the desire and ability to distance themselves from the poor. This desire arises from several sources. One is the search for status (prestige and respectability); the poor are often perceived as uncouth, ignorant, or disreputable, and the nonpoor gain status by disassociating themselves from the poor. This is especially true if, as is often the case, the poor belong to a stigmatized racial or ethnic group. One’s address becomes a prestigious status symbol if one lives in an area reserved for the “right” kinds of people. Such class consciousness coupled with aversive racism creates a related motive for concentrated poverty: fear of declining property value and/or the desire for property value appreciation. When the poor and/or racial-ethnic minorities are seen as harmful threats to community health and stability (e.g., lowering the quality of schools, raising the crime rate, spreading disease, not keeping up their yards or homes), then attempts to exclude them are made, which if successful leaves them in areas of highly concentrated poverty. On the other
hand, if efforts to exclude the poor are unsuccessful and some do enter a neighborhood, then under certain conditions, a self-fulfilling vicious circle of out-movement and avoidance of the area by the affluent coupled with declining property values occurs, as affluent people refuse to pay "top dollar" for housing in or close to areas in which "the undesirables" live and instead move to other more secure, better locations.

METHODS OF EXCLUSION
Historically, the institutionalized mechanisms the affluent have utilized to distance themselves from the poor, thereby relegating those with low incomes to impoverished areas, are restrictive covenants, zoning ordinances, building codes, and political control over the location of public housing projects. With these devices (which control the types and size of housing units that are built, the size of the lots homes are built on, and whether or not apartments are allowed to be built) those in control create sections of cities or whole towns that are simply too expensive for poor people to live in. Beyond these forms of class exclusion, African Americans have faced racial exclusion (e.g., denial of mortgage loans for homes in suburban areas). This combination of restrictions forced most middle- and working-class black households to live near or in predominantly poor black areas, thereby minimizing their ability to accumulate wealth through appreciating values of their homes. Since 1980, as successful blacks became able to obtain better housing outside old black city neighborhoods, the out-movement of the middle- and working-class—in combination with loss of jobs due to deindustrialization, plus minimal investment in poor urban areas by government and the private sector—left many areas devastated with extraordinarily high rates of poverty. In rare instances, such as in Mt. Laurel, New Jersey, some state courts have ruled that suburban towns' reliance on exclusionary land use control to keep the poor out of their towns and penned up in high poverty sections of cities, like Camden or Newark, is illegal. In the 1990s, programs aimed at increasing home ownership among blacks and replacing public housing projects with mixed income developments have reduced the extent of concentrated urban poverty.

CAUSES OF DETERIORATION
A slum is more than an area of concentrated poverty; it is an area of physical and social deterioration. Several mechanisms cause this deterioration. One is "red-lining" by financial and insurance institutions. Older areas with less affluent residents are perceived as not profitable enough for home or business loans and insurance coverage, which prevents the repair and improvement of dwellings and buildings. Inability to obtain insurance coverage makes it difficult or unwise for businesses or home owners to remain in red-lined neighborhoods. Absentee landlords and speculators also play a role if they are unwilling or unable to properly maintain properties and instead extract from their buildings maximum rent while investing the minimum in upkeep, until they become dilapidated or uninhabitable. Boarded up or semi-abandoned buildings get used by transients or for drug use and become the objects of arson (for insurance money or "kicks"), and a "broken windows" phenomena may emerge as residents or outsiders commit further damage and criminal acts because they see nothing to restrain destructive impulses (Wilson and Kelling 1982). Outsiders dump garbage in the neighborhood, crime increases, and most people who seek to better themselves leave the area if they are able.

LIFE AND CHARACTER

Adam Smith was born on June 5, 1723, in Kirkcaldy, Scotland, a posthumous child. His mother was in her early twenties, and she was widowed after less than three years of marriage. The bond between mother and son was very close, and as Smith never married, those who believe in psychoanalytic explanations have seen significance in this. Whenever it was feasible he lived with his mother, and a spinster cousin joined them in the 1760s.

Smith went to Glasgow University in 1737 at age fourteen. In 1740 he was sent to Balliol College, Oxford, where he stayed until 1746. Smith declined entering the church, a profession many thought advisable, and spent two unemployed years back at home in Scotland. Lord Kames and other friends then invited Smith to lecture on Rhetoric and Belles-Lettres in 1748, as a reigning Scottish fashion was to learn how to speak and write English like the English. Smith was considered a capital instructor for this purpose, and his lectures were well attended.

In 1751 Smith succeeded in being appointed to the professorship of moral philosophy at Glasgow. For the next twelve years his fame grew steadily, especially after the publication of his first book in 1759, *The Theory of Moral Sentiments* (*TMS*). *TMS* not only gave Smith a European reputation, it also appears to have gained him the position of tutor to the Duke of Buccleuch. This was a lucrative appointment, and it guaranteed Smith financial independence. Scottish University students paid their individual professors, and Smith behaved admirably in repaying his students their fees.

Smith had provided distinguished and valuable services to the university, not only as a teacher but also as an administrator. Since Smith's absentmindedness and lack of address are undoubted, having been noted in a variety of historical sources, Smith's success as an administrator shows that he had the ability to concentrate fully on a given task and to persuade his colleagues to do the same. He was college quaestor (treasurer) for six years, an unusually long term, and at the end of his time at Glasgow he was dean of faculty, vice-rector, and chairman of a special committee on internal university affairs. On accepting Smith's resignation, the university minutes record sincere regret "at the Removal of Dr. Smith, whose distinguished Probity and amiable qualities procured him the esteem and affection of his Colleagues" (Campbell and Skinner 1982, p. 125).

The European tour with the Duke of Buccleuch took nearly three years, and from 1764 to 1767 Smith had the opportunity to meet most of the eminent European literati, including the school of French economists known as the physiocrats. The lectures Smith delivered at Glasgow had dealt, in part, with economic topics, but it was during his stay in France that Smith appears to have begun writing *An Inquiry into the Nature and Causes of the Wealth of Nations* in earnest. Perhaps from 1764 onward, and certainly from 1767 to 1776, with very few interruptions, Smith's constant concern was the writing of his most prominent work.

Smith's appointment as commissioner of customs in 1777 was due to the influence of the Duke of Buccleuch with the prime minister, Lord North. A humorous consequence of his new position was Smith's realization that he had "scarce a stock, a cravat, a pair of ruffles, or a pocket handkerchief which was not prohibited to be worn or used in Great Britain." In order to set an example he "burnt them all" (Smith 1987, p. 245). As Smith's duties involved the control of smuggling, scholars have wondered how Smith could wish to punish the smuggler, who was not really blamable according to the dictates of natural liberty set out in *The Wealth of Nations*. The issues raised by Smith's acceptance of such a position have been most forcefully posed by the scholars Gary Anderson, William Shugart, and Robert Tollison: "The author of the *Wealth* and Commissioner Adam Smith were one and the same person … there is strong evidence that Smith sought the position and that it represented a reward not so much for intellectual accomplishment as for services he had rendered to the government" (1985, p. 742).

Consciously assertive of his originality, as early as 1755 Smith read a lecture strongly defending his priority for the idea of a system of natural liberty. Smith believed that several of his contemporaries, all major figures of the Scottish enlightenment, had plagiarized some of his thoughts. Adam Ferguson's (1723–1816) work on the division of labor and William Robertson's (1721–1793) economic interpretation of history provide two well-known examples of potentially plagiarized work while Hugh Blair (1718–1800) may have cooled relationships by his (acknowledged) use of Smith's lecture notes on the subject of rhetoric in Blair's *Lectures on Rhetoric* (1783). Smith had several eccentricities; among his personal habits, it was the absentminded consuming of sugar lumps, even in company; in conversation, he is said to have often taken opposite views of the same subject, according to his humor. Smith ended his days among admiring friends in Scotland, busy in his official duties and revising his publications, the last substantial revision being that of *TMS*. After ailing visibly for a while, Smith died on July 17, 1790.

EARLY WRITINGS

Smith's first love was rhetoric and literature. Dugald Stewart, Smith's successor to the Edinburgh chair, records that "the variety of poetical passages which he was not only accustomed to refer to occasionally, but which he was able to repeat with correctness, appeared surprising even..."
to those whose attention had never been attracted to more important acquisitions” (Rae 1965, p. 34). One of Smith’s most pleasant and instructive writings is the *Essay on the History of Astronomy,* which was published by Smith’s executors some five years after Smith’s death. The most interesting feature of the essay is Smith’s discussion of the principles that guide good philosophy and that hence serve to persuade readers. Smith asserts that “philosophy is the science of the connecting principles of nature” (Smith 1982, p. 45) and so good philosophy provides individuals connections from the familiar to the unfamiliar in such a natural manner that they are convinced of its truth. The essay considers the subject of astronomy from this perspective and concludes by praising the English physicist and mathematician Sir Isaac Newton (1642–1727) for providing “the greatest and most admirable improvement that was ever made in philosophy” (Smith 1982, p. 98). Smith was coy about the reality of the Newtonian system; his own principles suggest that all such systems are imaginary but he also wrote that the weight of evidence is such that one is forced to admit that the principles seem so natural, the arguments so well connected, and the evidence so overwhelming that one is insensibly led to speak of Newtonianism as real.

The most careful and sustained expositions of *TMS,* by twenty-first-century analysis the standard view, have been articulated by Alec Macfie, Roy H. Campbell, and David D. Raphael; the most interesting contrasts in the last two decades are those of Laurence Dickey and John Dwyer. Dickey argued forcefully that Smith changed his mind on the virtue of selfishness in the last edition of *TMS* (1986), while Dwyer showed how the circles Smith moved in were emphatic in asserting that the sympathetic passions were the most beneficial for society (1998).

Smith viewed moral philosophy as facing two main questions: What is the content of ethics and how does one come to accept one’s ethical precepts? He was very perceptive on the second question but only marginally illuminated the first. In modern language, *TMS* is probably best appreciated as a book on the socialization of morality rather than on the nature of right and wrong, which also explains why sociologists have been more struck with *TMS* than philosophers of ethics. Even though Smith did not illuminate practical ethics, it is notable that he insisted upon virtue being instinctive and not based upon calculation, as well as upon the reality of benevolence.

In *TMS,* humankind’s acceptance of moral rules is grounded upon the need for social approval. Individuals internalize morality by looking for the admiration of those who see them. This explanation serves well for children, or when adults are in company. Smith extended the application to adults who debate moral problems when alone by introducing the concept of an “impartial spectator”—someone who examines one’s moral quandaries with detachment and whose approval serves to sustain us when we suffer reverses of fortune.

The standard view argues that the sympathetic imagination of *TMS* leads to humankind’s codes of ethics and of law, while self-interest is the basis of economic behavior; the conflict between *TMS* and *The Wealth of Nations* is only apparent because the two books deal with different levels of social reality. Posthury has accorded fame to *The Wealth of Nations* and only appreciation to *TMS* because the link between self-interest and economic phenomena can be satisfactorily indicated, while a link of similar clarity between sympathy and ethics still awaits us. A late twentieth-century trend to interpret Smith’s economics through the lens of *TMS* faces the difficulty that only in the preface to the last edition of *TMS,* shortly before his death, did Smith make any public attempt to mention the two books together. Five editions of *The Wealth of Nations* (and of *TMS*) came and went without Smith ever trying to soften *The Wealth of Nations* with *TMS.* Scholars argue that if Smith had wanted modern-day readers to qualify the selfishness of *The Wealth of Nations* with the stoicism of *The Theory of Moral Sentiments* he would have done so himself.

**THE WEALTH OF NATIONS**

The manner of writing of *The Wealth of Nations* is modern in its frequent separation of theory from policy. In Books I through IV, Smith explained that free trade is the ideal policy for all nations. In Book V he explained the obvious practical requirement that governments must raise taxes to meet essential expenses. So the combined effect of all five books is to advocate a policy that imposes taxes for revenue but not for protection. This is the same policy that was supported in the popular literature of the 1740s in the pamphlets of William Richardson and Sir Matthew Decker. However, the separation of pure theory, which supports free trade, from practical policy, which recognizes the need for taxes, makes the ideas of *The Wealth of Nations* more attractive.

Much of the charm of Smith’s work arises from the casual fluidity of his language. He expressed commonplace ideas forcefully and provided homely illustrations; Smith’s arguments are axiomatic, but he interrupted his exposition with much ordinary illustration. These nuances in his writing have led modern-day scholars to frequent, and perhaps endless, discussion about whether he was really inductive or deductive. Perhaps the most effective use of everyday thought was the phrase “invisible hand” to describe the harmony of the market. Moral philosophers had consistently rejected the use of the market as socially beneficial because they could not fathom how the universal prevalence of selfishness—the motiva-
tion of the market—could lead to a harmonious society. It was one of several euphemisms used by contemporaries to refer to God as the beneficent controller of the universe. When Smith came to proving this difficult point, he found it convenient to finesse the argument by referring instead to the invisible hand as one that provides coherence through the market. Smith knew he could count on the subliminal persuasiveness of the “invisible hand” to quash any doubts readers might have about the goodness of the market. Ferguson and Robertson, while serving as army chaplains, had each used the phrase to exhort their soldiers in 1747. Whether Smith himself believed in a Christian God is beside the point; it is his rhetorical skill that needs to be appreciated.

The fairest treatment of Smith's contributions to economic theory would portray Smith’s ideas along with those of his contemporaries. Space does not permit and readability perhaps does not require such discussion. With a brief glance at contemporary thought, the focus herein is on the internal logic of Smith’s arguments, with the topics being chosen by their importance for modern economics. In considering Smith’s contributions to economic theory it is useful to begin with microeconomics, then to macroeconomics, and finally to international trade.

Jacob Viner provided a penetrating assessment of Smith’s contributions to microeconomics when he wrote, “On every detail, taken by itself, Smith appears to have had predecessors in plenty. On a few details was Smith as penetrating as the best of his predecessors” (1928, p. 118). The theoretical constructs of demand and supply, used by modern economists, had been widely and effectively used by economists for more than a century when Adam Smith wrote. A brief overview of Smith’s microeconomic theory shows that Smith’s attempted innovations were severely limited.

Smith distinguished between “natural” and “market” price, regarding the former as clearly the more fundamental of the two. What then determines natural price? Smith began by explaining to readers that in every society, at any given time, there exists an ordinary or average rate of wages, profits, and rents; these average rates for each factor of production Smith called the natural rate. He then defined the natural price as the sum of the natural rates of wages, profits, and rents. This price is distinguished from the market price, which is merely another name for whatever price reigns in the market at any given time. The demand of those individuals who are willing to pay the natural price of a commodity constitutes what is called the “effectual demand,” and market price is said to arise out of the interplay of the actual supply and the desires of the effectual demanders. The explicit theoretical construct thus consists of an awkward juxtaposition of a point supply and a point demand. If, however, one glosses over the location of equilibrium, that is, the natural price, and asks instead how Smith described what happens when the world is not in equilibrium, the treatment is excellent.

Since natural price is defined as the sum of natural wages, profits, and rents, this requires an explanation of the natural rates of wages, profits, and rents. The natural rates are naturally regulated by the structure of the economy and its growth, “partly by the general circumstances of the society, their riches or poverty, their advancing, stationary, or declining condition; and partly by the particular nature of each employment” (1976, I, 72, 159). The subsequent chapters, however, fail to show readers how to use structure and growth to find natural wages or profits in any particular situation.

Smith had claimed that product prices are to be explained by factor prices; this dichotomy between the forces determining product and factor prices was an innovation. He subsequently claimed that factor prices, and hence product prices, are to be explained by structural and growth factors. Somehow, microeconomics has disappeared. The procedure has led some rigorous critics such as Mark Blaug, to exclaim, “To say that the normal price of an article is the price that just covers money costs is to explain prices by prices. In this sense, Adam Smith had no theory of value whatever” (1985, p. 39).

How did Smith convince so many ordinary readers of the merits of the market? He does provide readers many convincing illustrations of opportunity cost and of the equalization of returns in different uses. Chapter X of Book I deals with the inequalities of wages and profits across different occupations. It is a beautiful exercise in tracing how differences in prestige or risk can account for such inequalities in money wages. While such explanations can be couched in the modern language of demand and supply, since Smith did not apply the modern apparatus, one has to ask if there are other, perhaps simpler, ways of getting to such results.

Suppose Smith began by assuming that any violation of natural liberty was both morally wrong and economically harmful; such a position could itself provide the grounds to condemn several institutions of Smith’s day. Such “politically based” arguments are convenient in that they need to consider the absence of competition on only one side of the market. For example, in the case of the Law of Settlements, which hindered the mobility of workers, it was enough to condemn the Laws that the rights of workers were being violated. Second, if one assumes that a market reaches a stable equilibrium, then the belief in one-sided competition alone suffices to provide several analytical results. For example, in the usual version of Ricardian rent theory, the same final outcome is reached whether only farmers compete (for land) or only landlords compete (for farmers). This one-sided analytical proce-
dure works best when there are constant returns to scale and the assumption of fixed proportions, used on several occasions by Smith, is perhaps a consequence of his analytical method.

Smith's contribution to microeconomics requires some care to elucidate: He did not advance scholars' understanding of the equilibrium theory, involving demand and supply; he even confused matters by dichotomizing product and factor prices. But, from his very earliest lectures, Smith thoroughly appreciated the fundamental fact that liberty and competition lead to zero-profits. This observation was repeatedly and successfully applied to such fields as the choice of occupations, the preference for pasturage over tillage, and the determination of joint prices. It even sufficed to move analysts toward the "natural price," wherever that might be. It is a form of argument that is attractive, easy to learn, and independent of the more intricate demand-supply apparatus, and accounts for Smith's hold on the general public.

There is no direct concern for macroeconomic problems in *The Wealth of Nations*. By omitting any systematic discussion of unemployment in *The Wealth of Nations*, Smith made macroeconomic concerns seem chimerical and succeeded in focusing attention on capital accumulation and upon long-run issues. So perhaps the most notable victory of *The Wealth of Nations* was a silent one. When Smith did touch upon unemployment, the primary concern for his contemporaries, he used three separate arguments to de-emphasize that concern. Smith provided readers with a model of the economy as a giant corn farm, which employs workers by keeping aside a portion of last year's harvest in order to feed the workers until the next harvest. Smith called this the "wages fund," and since it is predetermined by last year's decision, one cannot increase the numbers to be employed since the model provides the food for only so many. A second argument claimed that the soldiers disbanded after the Seven Years' War found new jobs within a short space of time, and Smith used this as proof that persistent unemployment is not a real possibility. Finally, Smith made the "global" assertion that "what is annually saved is as regularly consumed as what is annually spent, and nearly in the same time too; but it is consumed by a different set of people" (1976, I, 337-338). The implication that aggregate demand always equals aggregate supply, regardless of how much or little is saved, probably had great impact upon Smith's contemporaries. The cumulative impact of the several arguments was to suggest to readers that the market economy is globally stable, and if only it were left free, it would also be efficient.

An important idea, never quite explicitly stated yet pervading the entire book, is the superiority of commercial society over feudalism. This led Smith to the concepts of productive labor, which roughly correspond to economic activity that produces a measurable output, and to contrast it with unproductive labor or services. Without such a framework, one would be hard pressed to explain why a fully employed commercial society, making cloth and machines, is superior to a fully employed feudal one, making swords and monasteries. Much of the framework of modern national income accounting is set up at different points of *The Wealth of Nations*. To grasp the concept of national income one has to have all of a nation's economic activity in one's mind. A very important by-product, appropriate to someone who believed in unintended consequences, was the image of the economy as a whole. This constantly recurring background to all parts of *The Wealth of Nations*, the image of the economy as a complex machine always working away, has led scholars, such as Samuel Hollander, to argue that Smith was an early general equilibrium theorist (1976).

The effort to conceive of the economy as a whole and represent it by some number had a second potent conclusion. Since bundles of apples and oranges cannot be compared physically but only as economic values, the numerical concept led to a focus upon monetary values. In turn, this enabled Smith to conclude that growth is not based upon acquiring a surplus of some physical balance, as with mercantilism and bullion or with physiocracy and agriculture, but rather a value surplus—that of income over expenditure. In this sense, it has been well said that Smith's novelty lay in the cumulative "shifts of focus" in *The Wealth of Nations* (Winch 1996, p. 22).

The issue that bridges macroeconomics and trade is monetary policy. Smith broke cleanly with the past and argued that the market was sufficient to provide whatever amount of circulating medium was necessary. Mercantilist arguments in favor of an influx of metals as a wartime buffer or for providing ample liquidity to the markets were all specious. Just as one does not try to regulate trade in pots and pans but trusts the market to provide them as needed, so too could the market suffice for money.

To attempt to increase the wealth of any country [by interfering with the trade in gold and silver] ... is as absurd as it would be to increase the good cheer of private families, by obliging them to keep an unnecessary number of kitchen utensils (Smith 1976, IV, pp. 439–440).

From the time of publication of *The Wealth of Nations* until the middle of the twentieth century, Smith was viewed primarily as the source of laissez-faire ideas. According to Wesley Mitchell in his *Types of Economic Theory* (1967), the benefits of economic freedom can be argued on the basis of three axioms:

1. Individuals desire to maximize their wealth.
2. Individuals know better than governments how to maximize their own wealth.

3. National wealth is the sum of individual wealth (1967, pp. 61–64).

Axioms 1 and 2, in conjunction, prove that individual wealth is maximized when government leaves individuals alone. Axiom 3 then says that maximizing individual wealth suffices to maximize national wealth. If one describes the axioms loosely as greed, knowledge, and additivity, then greedy and knowledgeable individuals surely do not need government in order to maximize their wealth, and additivity suffices to assure one that, since the aggregate is the simple sum of the individuals, the aggregate also does not need government to maximize economic growth. Modern readers, familiar with externalities in the form of, say, pollution, will probably be most curious about the validity of axiom 3, but in most developing economies axioms 1 and 2 are also worth questioning.

The two most important policy measures of Smith’s time were bounties for infant industries in foreign trade and preventing speculation in food markets in domestic trade. Smith firmly rejected both bounties for infant industries and interference in food markets. He argued the case against bounties as follows: He noted that no one argues against natural advantages, and he went on to illustrate this with his famous example of growing grapes in hothouses in Scotland. Then he transferred the argument without any further reasoning to cases where there is no suggestion of natural advantage. “Whether the advantages which one country has over another, be natural or acquired, is in this respect of no consequence” (1976, IV, p. 458). One could ask how others acquired such an advantage and why anyone might not acquire it as well? This is just what all economists who urged “catch-up” to their countries did argue. Smith could have said that choosing which infant industries have promise requires too much knowledge and discrimination or that such infants have a persistent tendency not to want to grow up. He did neither. So strong was his feeling on the matter that he simply bypassed the argument.

If one wonders about the incongruity of the putative father of economics providing so many examples of indifferent economic analysis, one should remember that a critic found many proofs in Euclid’s Elements to be “more complicated than older versions … essential axioms of order and separation are entirely overlooked, the postulates inadequate to prove even the first theorem” (Goodstein 1951, p. 3). Modern-day scholars seem to remember historical figures as much for their intentions as for their achievements. Smith wrote at a time when his liberal cosmopolitanism won him many converts, especially outside Britain; the support of elite politicians probably mattered, especially when Smith could be used in support of conservative economic policies during scarcities; and the benefits to Britain of appealing to free trade when Britain was the leader in manufacturing meant that economic truth was supported by self-interest. How far Smith’s superior fame was due to these noneconomic factors is a question that only bias can solve.

It is appropriate to close by continuing with the words of Jacob Viner who wrote of Smith that he was only applying to society forms of reasoning that had long been utilized by theologians and philosophers to general phenomena and that only on a few details was Smith’s analysis superior: “But Smith made an original forward step when he seriously applied himself to the task of analyzing the whole range of economic process with the purpose of discovering the nature of the order which underlay its surface chaos” (1928, p. 118). It was not so much any refinement in analysis but Smith’s ambitious undertaking and his faith in the overall harmony of free trade that constitute his principal legacy.

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION
SMITH, VERNON L.
1927–

American economist Vernon Lomax Smith was born in Wichita, Kansas, on January 1, 1927. In 2002 Smith became the co-laureate of the Nobel Prize in Economics “for having established laboratory experiments as a tool in empirical economic analysis, especially in the study of alternative market mechanisms” (Nobel Foundation 2002). In awarding Smith the prize, the Nobel committee recognized the well-known observation that Smith is the father of the discipline of experimental economics.

Smith’s official Nobel autobiography (Nobel Foundation 2002) provides a moving description of life in the Depression-era Kansas of railroads, farming, oil drilling, and relatives who die too young. This was also a world in which a graduate of a one-room schoolhouse who became a distracted “C” student in high school could gain admission to one of the world’s finest universities, the California Institute of Technology (Caltech), by passing the rigorous admission exam. By 1955 Smith was a graduate of Caltech (B.S., 1949), the University of Kansas (M.A., 1951), and Harvard University (Ph.D., 1955), with a faculty position at Purdue University in Indiana.

Smith’s initial research areas were in capital theory, investment, and financial economics. At about this time, a fortunate synergy among teaching and research emerged. The behavior of the stock market is certainly relevant to capital theory and financial economics, and Smith pondered how to get these ideas across in his classes. He recalled from his days as a graduate student at Harvard that economist Edward Hastings Chamberlin (1899–1967) had created a simulated “random meetings” market in a classroom, in which demand and supply curves were constructed from hypothetical benefits and costs assigned to the students. Chamberlin’s markets famously failed to find the competitive equilibrium. Smith’s changes were initially to use a different trading institution, the oral double auction (an analog of stock exchange trading rules), and to repeat the markets across time. Later, after conversations with psychologist Sidney Siegel (1916–1961), Smith made a third important innovation: costs and valuations were no longer hypothetical, and participants were actually paid according to their earnings. The Chamberlin findings dissolved; the markets converged to the competitive predictions. Smith’s first research results in experimental economics were published in the Journal of Political Economy in 1962. Further exploration of the double auction institution followed. Then, Smith applied the methodology to a different institution, the sealed bid auction (as used in U.S. Treasury securities auctions). Along the way, Smith continued to make seminal contributions in financial economics, environmental economics, and economic anthropology.

During a visiting appointment at Caltech in 1974, Smith found that a former Purdue faculty member, Charles Plott, had moved to Caltech and become an enthusiastic proponent of experimental methodology. This began a period of fruitful collaboration between them. Smith left for the University of Arizona in 1976 and then George Mason University in 2001. Smith’s reputation as the “father of experimental economics” coalesced, due not only to the original Purdue innovations but also to the breadth of his new applications and the development of key methodology treatises on laboratory experiments. In the former category, Smith’s work expanded to include public goods provision mechanisms, oral auctions, industrial organization, asset pricing, and the concept of computer assisted “smart markets.” His methodological articles address the concept of “induced valuation” (reflecting his earlier decision to pay subjects based upon earnings). In 1982 his tour de force, “Microeconomic Systems as an Experimental Science,” was published. Nationally and internationally, the number of researchers adopting the methodology increased dramatically. Smith was the driving force behind the founding of the Economic Science Association in the mid-1980s.

In his Nobel autobiography, Smith singles out two books in economics that attracted his attention prior to graduate school, one by American economist Paul Samuelson, the other by Austrian economist Ludwig von Mises (1881–1973). This observation is a foreshadowing of Smith’s career. His lifetime of contributions to traditional mathematical microeconomic theory (the Samuelson stream) by themselves would be stellar, but his work in experimental economics is equally important. For Smith, experimental economics is immersed in a different way of looking at the world. Smith’s mother had strong socialist leanings, and his graduate training at Harvard in the early 1950s was hardly an incubator for a libertarian worldview, certainly not foreshadowing his later active involvement with the Mont Pelerin society. But Smith’s economics (not merely his experimental economics) are very different from that which his early background might suggest. This could be due to his early reading of von Mises...
and German economist Friedrich von Hayek (1899–1992). It could also reflect the striking observation from his first experiments: markets that do not efficiently capture gains from exchange under one institution will do so under another. Whatever the history, there is no better place to find Smith’s views than in his 2002 Nobel lecture, “Constructivist and Ecological Rationality in Economics.” The lecture has obvious overtones of Austrian economics, but Smith presents a tantalizing paradox. Experimental economics can be viewed as buttressing a Hayekian view of economics, but Hayek himself seemed to anticipate, and then reject, the methodology of experiments.

SMOKING

Cigarette smoking has great societal and clinical significance. It is a major cause of several diseases, including a variety of cancers. The practice of cigarette smoking is pervasive; about a quarter of all adult Americans smoke cigarettes, and smoking rates are even higher in many other countries. Despite the high personal cost associated with cigarette smoking, it is a prototypical addictive disorder manifesting such features as tolerance, withdrawal, and chronic use. The peak age for smoking prevalence is between eighteen and twenty-five years. Retrospective data from the National Household Survey on Drug Abuse suggests that the average age of first use of tobacco products in 1999 among all persons who ever used in their lifetime was 15.4 for cigarettes, 20.5 for cigars, and 16.7 for smokeless tobacco across all age groups (Kopstein 2001). Data from the National Comorbidity Survey suggests that the onset of nicotine dependence is delayed for at least one year after the onset of daily smoking. Smoking rates decline among people who have reached their mid-twenties, but these declines are modest in comparison to other forms of substance use. This may be due to the fact that cigarette smoking is highly addictive, legal, and not immediately performance-imparing.

**BIOLOGICAL ASPECTS OF NICOTINE ADDICTION**

Nicotine, independently, yields the trademark effects of an addictive drug. It produces tolerance and physical dependence, and heightened doses produce euphoria and satisfaction (Corrigall 1999; USDHHS 1998). Smokers will not self-administer tobacco on a chronic basis if it does not contain nicotine. Nicotine is essential for the development and maintenance of a smoking habit. However, once nicotine dependence is established, cues related to nicotine release become greatly influential in controlling self-administration behaviors. When a cigarette is smoked, about 80 percent of the inhaled nicotine is absorbed in the lungs (Armitage et al. 1975). Absorption is both efficient and extremely rapid. Despite the overall recognition that the rapid onset of drug action promotes addictive drug use, it remains unclear why this is so. Researchers do not fully understand which characteristics of drug pharmacokinetics are most determinant of addictiveness.

**BEHAVIORAL ASPECTS AND ENVIRONMENTAL INFLUENCE**

Data published in 2002 suggest that smoking among American adolescents is fairly common, with 27 percent of twelfth graders, 18 percent of tenth graders, and 11 percent of eighth graders reporting that they had smoked in the past month (Johnston et al. 2002). This level of smoking prevalence represents a decline from peaks in the mid-1990s. Much less is known about the epidemiology of tobacco dependence in adolescents. *Dependence* is a term often correlated with addiction, and adolescent smokers are less likely to be diagnosed with tobacco dependence than are adult smokers (Colby et al. 2000), although many adolescent smokers consider themselves addicted. Adolescents who are dependent report the same symptoms as do dependent adults, including cravings, withdrawal, tolerance, and a desire to reduce smoking (Colby et al. 2000). Compared to adults at the same level of self-reported intake, adolescents who smoke are more likely to be diagnosed as dependent, which suggests that adolescents may be especially vulnerable to dependence or sensitive to the effects of nicotine (Kandel and Chen 2000).
Before they experiment with cigarettes, adolescents form beliefs and attitudes about the effects of smoking. These attitudes and beliefs prospectively predict both the onset and escalation of smoking. Many adolescents believe that there are no health risks related to smoking in the first few years, and they believe that they will stop smoking before any damage is done. Existing evidence suggests that adolescents and adults exhibit unrealistic optimism about the personalized risks of smoking (Arnett 2000; Weinstein 1999). Whether adolescents are any more likely than adults to underestimate the personalized risks of smoking is unclear.

Evidence indicates that as smokers become more dependent, there is a shift in the motivational basis for their tobacco use. Social motives and contextual factors are rated as influential to beginner smokers, while heavy smokers emphasize the importance of control over negative moods and urges, and the fact that smoking has become involuntary (Piper et al. 2004). When smoking becomes less linked to external cues and more linked to internal stimuli, smokers are classified as dependent. There is also evidence suggesting that smoking cigarettes may lead to the use of illicit drugs. Cigarette smoking is endemic among substance abusers, with rates as high as 74 percent to 88 percent (Kalman 1998), compared to 23 percent of the general population (CDC 2002).

Greater parental education is associated with less likelihood of smoking in offspring. Additionally, girls appear to be more influenced by peer smoking than boys (Mermelstein 1999). In the United States, the highest smoking rates are among American Indian and Alaska Native adolescents, followed by whites and then Hispanics, with lower rates among Asian Americans and African Americans. While studies that sample multiethnic groups are sparse, research has suggested that African American and Asian American adolescents report stronger antismoking socialization messages from parents and that African American parents report feeling particularly empowered to influence their children’s smoking (for reviews, see Mermelstein 1999; USDHHS 1998). Peer smoking is a relatively weak predictor of smoking for African American adolescents compared to white adolescents.

Adolescents sometimes start smoking as a result of self-image. The social image of an adolescent smoker is an ambivalent one, with negative aspects but also images of toughness, sociability, and precocity that may be particularly valued by “deviance-prone” adolescents who are at risk to smoke (Barton et al. 1982). Additionally, adolescents may start smoking and continue smoking because of their perception of the effect that smoking has on weight control and dieting. The belief that smoking can control body weight has been shown to predict smoking initiation among adolescent girls, but not boys (Austin and Gortmaker 2001). In addition, this belief is held more widely by white girls than by African American girls (Klesges et al. 1997). Despite the above-mentioned indicators, peer smoking is the most consistently identified predictor of adolescent smoking (Derzon and Lipsey 1999). In addition to cigarette smoking by peers, affiliation with peers who engage in high levels of other problem behaviors also prospectively predicts smoking initiation, as does self-identification with a high-risk social group (Sussman et al. 1994).

SMOKING CESSATION AND PREVENTION

The tobacco industry spends millions of dollars per day on advertising and promotional materials to keep their products in the public eye. Beyond such reminders of the availability of tobacco products, smoking is not an easy habit to break. Smokers must not only break the physical addiction to nicotine, but also the habit of lighting up at certain times of the day. Successful quitters confess that quitting is often a lengthy process that involves several unsuccessful attempts. Although one-third of smokers attempt to quit each year, 90 percent or more of those who attempt to quit will fail.

Nicotine replacement therapies (NRTs) have been used to help some people quit smoking. The two most common forms of NRTs are chewing gum and the nicotine patch, both of which are available over the counter. Nicorette, a prescription chewing gum containing nicotine, is often used to help reduce the consumption of nicotine over time. Users have reported experiencing fewer cravings for nicotine as the dosage is reduced, until they are completely weaned. The nicotine patch was first marketed in 1991 for smokers with a desire to quit. Generally, the nicotine patch is used in conjunction with a comprehensive smoking-behavior cessation program. Additionally, a nicotine nasal spray, nicotine inhaler, and nicotine pill have been approved by the FDA to help cigarette smokers quit smoking. In order to prevent the initiation and maintenance of smoking, there has been an increase since the mid-1980s in the development and implementation of smoking cessation and prevention programs, especially for young people and adolescents.

GLOBAL ECONOMICS OF SMOKING

Approximately 80 percent of the world’s 1.1 billion smokers live in low- and middle-income countries. In 1998 about four million people died of tobacco-related disease worldwide (WHO 1999). This number is projected to increase to ten million annually by 2030, with 70 percent of these deaths occurring in low-income countries. Death counts of this magnitude could be prevented if current smokers quit, but it is rare for smokers living in low-
middle-income countries to attempt to quit smoking (Jha and Chaloupka 2000). Although few dispute that smoking is damaging to human health on a global scale (Peto and Lopez 2000), governments have avoided taking action to control smoking. This is mainly due to concerns that such interventions might have harmful economic consequences, such as permanent job losses. Despite these concerns, several common measures aimed at the control of smoking, such as higher tobacco taxes, consumer information, bans on advertising and promotion, and regulatory policies, have had a significant impact. Each will be discussed below.

An increase in tobacco taxes is the single most effective intervention to reduce the demand for tobacco. A review by Prabhat Jha and Frank Chaloupka (2000) suggests that a price increase of 10 percent would reduce smoking by 4 percent in high-income countries and by about 8 percent in low- and middle-income countries. This evidence also implies that young people, individuals on low incomes, and those with less education are more responsive to price changes (Chaloupka et al. 2000). Policies to improve the quality and extent of tobacco information can also reduce smoking, particularly in low- and middle-income countries. For example, in the 1960s and 1970s, the promulgation in the United States and Britain of new evidence on the health risks of smoking helped reduce consumption between 4 and 9 percent. In addition, warning labels on cigarette packages were also found to reduce consumption during that era (Kenkel and Chen 2000). In a review of 102 countries and econometric analyses of income, Henry Saffer and Chaloupka (2000) revealed that bans on advertising and promotion led to considerable reductions in tobacco consumption.

Enforcing regulatory policies designed to prevent smoking in public places, worksites, and other facilities can also significantly reduce cigarette consumption worldwide (Yurekli and Zhang 2000). Attempts to impose restrictions on the sale of cigarettes to young people in high-income countries have mostly been unsuccessful (Siegel et al. 1999). Furthermore, it may be difficult to implement and enforce such restrictions in low-income countries. Evidence indicates that freer trade in tobacco products has led to an increase in smoking and other types of tobacco use. One solution is for countries to adopt measures that effectively reduce demand and apply those measures to both imported and domestically produced cigarettes (Taylor et al. 2000).

BIBLIOGRAPHY

The concept of representing transactions between actors in an economy in the form of a matrix was first introduced by Wassily Leontief in his classic work *The Structure of American Economy* (1941, 1951). For Leontief, the actors were mainly producing sectors, and the matrix represented intermediate inputs in production. In dealing with problems of income generation in its relation to employment, the quantities of consumers’ goods and services absorbed by households can be considered (in a Keynesian manner) to be structurally dependent on the total level of employment in the same way as the quantities of coke and ore absorbed by blast furnaces are considered to be structurally related to the amount of pig iron produced by them. (Leontief 1966, pp. 141–142)
From these conceptual foundations, Leontief extends the input-output matrix to include transactions between households, factors of production, and so on.

The applications of SAMs can be wide-ranging. They can, and often do, form the backbone of computable general equilibrium models. SAMs are particularly useful for any exercise in which a researcher or policy maker is interested in analyzing the distributional implications of particular policy measures (Pyatt and Round 1979, 1985, and 2006). In such cases, the overall matrix multiplier (which gives the total “activity” level of all the actors in an economy to produce a given level of final use as the sum of direct activity levels and an infinite series of indirect ones) is typically broken down into a number of multiplicative components (Pyatt and Round 1979). Each of these components represents a particular connection between or within groups’ effects. An analysis of these disaggregated multipliers not only tells us the effects of an injection of a particular shock to various socioeconomic groups, it also tells us the mechanisms through which such effects come about. There are now many studies that construct SAMs for developing countries and examine the distributional consequences of policy measures (Pyatt and Round 1985). One hopes that as time goes by, SAMs for more and more countries will be constructed, as they could only help in the formulation and effective implementation of development policies benefitting the poor.

SOCIAL ANXIETY

Social anxiety refers to the fear of being humiliated, embarrassed, negatively evaluated, or rejected in social situations. A common human experience, social anxiety exists on a continuum of severity from infrequent and mild feelings of discomfort in social situations to chronic and pervasive distress in many different social settings. An individual’s experience of social anxiety may be limited to one specific type of social situation, such as public speaking, or it may be so pervasive that anxiety and fear are experienced in nearly any situation in which other people are present. When an individual’s social anxiety is excessive and results in significant distress or impairment, the person may be diagnosed with social anxiety disorder (or social phobia).

Social anxiety disorder is the third most prevalent psychiatric condition in the United States, with a lifetime prevalence rate of approximately 13 percent in the general population. The majority of individuals with excessive social anxiety, or social anxiety disorder, also report comorbid anxiety, mood, or substance abuse (e.g., alcohol) conditions. Although excessive social anxiety is a relatively common psychological condition, the exact cause of the phenomenon remains unclear. Several researchers have noted the possibility of a genetic predisposition for social anxiety that appears to contribute to familial patterns of the condition. Developmental researchers point to temperament characteristics in shy, fearful, and behaviorally inhibited children and the increased likelihood that these children will develop excessive social anxiety later in life. Other researchers believe that a predisposition may interact with early learning to reinforce the perception that social interactions are threatening and that estimated costs of social failures outweigh the possible benefits (e.g., intimacy).

As a coping strategy, people with excessive social anxiety often attempt to alter or control negative feelings associated with social evaluative concerns and avoid or escape situations in which these feelings may occur. These efforts may lead to increased apprehension of future social events, increased use of alcohol and other maladaptive coping strategies (e.g., rumination), and social withdrawal and isolation. As a result, excessive social anxiety is related to functional impairment in a variety of domains including school, work, leisure, and physical health. Socially anxious individuals also report a number of interpersonal problems, including fewer friends, less perceived social support, an increased likelihood of being single, and less romantic relationship satisfaction. Thus excessive social anxiety may be what therapists call a “life-limiting” condition in that it interferes with interpersonal functioning and results in fewer positive emotional experiences and events.
Social anxiety may be treated effectively with a variety of psychological and pharmacological interventions. Evidence suggests that both individual and group cognitive-behavioral therapy may be effective in reducing symptoms and distress associated with social anxiety. Cognitive-behavioral therapies tend to target dysfunctional thoughts, beliefs, and behaviors and teach individuals different, more adaptive, ways to manage their behavior and respond effectively in social situations. In addition, several medications, including benzodiazepines and the class of antidepressants called SSRIs (selective serotonin reuptake inhibitors) appear to be effective and well-tolerated.

SOCIAL CAPITAL

In a broad and nonessentialist sense, social capital means that the relations humans enter into are a potential source of utility and benefit for them. However, the concept of social capital is perceived in divergent ways with a plurality of approaches and empirical operationalizations. Unfortunately, there is little discussion among dissenting viewpoints.

After an earlier emergence in the work of Lydia Hanifan (1916) or Jane Jacobs (1961), the term social capital resurfaced in the 1970s in the work of economist Glenn Loury. For Loury, the social context in which one finds oneself embedded strongly conditions one’s achievement. This is profoundly evident whenever social divisions that structure inequalities, such as race or class, are at play. In such a context, Loury describes social capital as the impact of one’s own social position, which acts to further or impede the acquisition of human capital (the market-valued assets of education and skills) (Loury 1977, pp. 175–176).

PIERRE BOURDIEU, JAMES S. COLEMAN, AND SOCIAL CAPITAL

Pierre Bourdieu (1930–2002) was the first to conceptualize social capital in an explicitly sociological manner that is at variance with Loury’s view. For Bourdieu, capital consists of accumulated human labor that either assumes a distinct material form or an integrated form as part of an objective or subjective structure, the latter being the predispositions of mind and body (Bourdieu 2001, p. 98). Bourdieu also understands capital in the sense of power and resources (Bourdieu and Wacquant 1992).

Bourdieu is concerned with three forms of capital: economic, cultural, and social, each operating in a different field. Among them, social capital, which neither derives from nor is independent of the other forms, comprises social responsibilities, connections, or linkages, and under certain circumstances is convertible into economic capital. Bourdieu also considers the family to be a basic source of social capital, mainly found among the socially powerful in the upper middle class or haute bourgeoisie; the ideal-typical institutionalized form of social capital is the nobility title (Bourdieu 2001, p. 98). By contrast, the lower social strata do not possess capital, including social capital (Bourdieu 1986).

Social capital is formed, more or less consciously, via integration into networks. Unlike economic capital, social capital has no specific material form. It is also characterized by a certain indeterminacy, so that there can be, for example, a residual sense of unspecified obligation. Social capital is, in a sense, “suspended” in midair, like social structures. This, according to Bourdieu, is an inevitable dimension of social capital. If it were clear and specific, it would simply be a series of ordinary nonmarket transactions. Social capital, according to Bourdieu, is “the sum of active or potential resources that are connected through the possession of a network of permanent relations of mutual acquaintance and recognition, which are more or less institutionalized, or, in other words, with the inclusion into a group” (Bourdieu 1994, p. 90). Participation in a group provides each member “with the backing of the collectivity-owned capital, a ‘credential’ that entitles them to credit in the various senses of the word” (Bourdieu 2001, p. 103). Importantly, the agent of action is the separate individual member of the group.

Transactions between group members require a minimum degree of homogeneity, and the profits that accrue from membership form the basis of the solidarity that makes such transactions possible. Bourdieu clearly holds that the reproduction of social capital requires a continuous effort of “sociability” and continual repeated contacts during which mutual recognition by group members is confirmed in order to sustain group cohesion (Bourdieu 2001, p. 104).
For his part, while studying school failure and aiming at the reinforcement of human capital, James Coleman (1926–1995) came to regard social capital as a means of support. In particular, he claims that social capital strengthens students’ school and university performance and, therefore, the generation of human capital. This view is much in line with Loury’s conceptualization of social capital, yet here social capital is explicitly a positive and enhanceable quality (Coleman and Hoffer 1987; Coleman 1988).

Coleman uses this notion of social capital in connection with other forms of capital, such as economic-financial, natural, and human capital. Specifically, social capital results from changes that take place between individuals, facilitating social action (Coleman 1990, p. 302).

Coleman defines social capital on the basis of its function, as a range of entities with two common attributes: These entities are all aspects of social structures, and they all facilitate certain actions within structures, by individual or collective agents (Coleman 1988, p. S98). Social capital may assume three forms: “obligations and expectations, which depend on trustworthiness of the social environment, information-flow capability of the social structure, and norms accompanied by sanctions” (p. S119). Coleman, like Bourdieu, stresses the nonconcrete, nonmaterial, and indefinite character of social capital as compared to other forms of capital. However, in contradistinction to Bourdieu, he notes that unlike other forms of capital, social capital is a public good, because those who generate social capital enjoy only a limited part of its benefits (pp. S116–S118). Social capital is not solely a property or benefit of the individual agent who generates it, but also of other individuals, as well as of the community. Because social capital is embedded within the social context, certain characteristics of social relations can facilitate its appearance, including trust and reciprocity among the members of the inner-group, effective normative regulations, and open social structures (pp. S102–S105, S106).

It is important to distinguish resources from the ability to acquire them, through participation in networks or social structures. This distinction is clear in Bourdieu, but vague in Coleman. By equating social capital with the resources through which it is acquired, or which it creates, one is led toward tautology and a vicious circle. In this sense, it can be argued that Coleman’s conceptualization gets blurred and eventually loses much of its value.

ROBERT D. PUTNAM, SOCIAL CAPITAL, AND CRITIQUE
Parallel to the ongoing sociological interest in social capital, this notion has also been adopted by other disciplines. Political scientist Robert Putnam, for example, has developed his ideas in relation to social capital especially. He points out that social capital is formed by “features of social organizations, or social life—networks, norms, and trust—that enable participants to act together more effectively to pursue shared objectives” (Putnam 1995, pp. 664–665, emphasis added; Putnam 1993, p. 67).

Putnam broadens the notion of social capital from the level of individual and collective actors to the level of organizations and communities (Wollebaek and Selle 2002, p. 34; Portes 2000), and from there to social life as a whole. The latter includes cities, regions, and even entire countries. Coleman had already attempted such an expansion of meaning, as we have seen. However, the problem of silence relating to the supposedly neutral character of horizontal ties, raised in sociological discussions of Coleman’s definition of social capital, cannot be tolerated in Putnam’s conceptual transference. In the neoplaristic participatory context that the latter has adopted, differences in economic, social, or other forms of power do not raise a significant issue; hence what prevails is participation as such and the extent to which it appears.

Participatory attitudes within the context of community networks seem to generate additional forms of social capital. Thus, social capital can do the “bonding,” “bridging,” or even “linking” of social groups. This means, respectively, forming ties between people in similar situations, bringing together people in different situations who belong to different social groups (Svendsen 2006), and mustering heterogeneous social groups together (Woolcock 2001). All result in synergies that effect positive outcomes in virtually all fronts. Undoubtedly, in this way networks appear to be vehicles of social capital.

In fact, in Putnam’s approach, social capital stock is equal to the participatory attitude in a community. Specifically, social capital is not researched directly, but instead proxies are used: Social capital is operationalized through indices such as, primarily, the degree of participation in volunteer organizations (Welzel et al. 2005, p. 121); trust toward authorities or others; the reading of newspapers, which reflects an interest in public affairs; and similar indices that mostly apply to the mezzo- and macro-levels (Putnam 2000). So, the key in researching social capital is the keenness of participation, or more broadly civic values or the ethos of “civicness” from which willingness to participate originates.

Attempts at deconstruction and critical recomposition of social capital have been made by sociologist Alejandro Portes and his associates, among others. Portes and Julia Sensenbrenner (1993) suggest a clear distinction between the sources of social capital and the results of its action. They recognize four sources from which social capital originates: (1) internalization of values; (2) transactions of a reciprocal character; (3) forms of collective
solidarity; and (4) the trust imposed by negative or positive sanctions. It is accepted that the sources of social capital are embedded in the motives of network/group members to provide resources. These include consummatory motives, and those cultivated within the community, with solidarity strikes being a typical case. They may also originate from instrumental motives involving the expectation of reciprocity and trust (e.g., the sponsor is secured against fraud) (Portes and Sensenbrenner 1993; Portes 1998, p. 8).

The various sources of social capital lead to its composite formation so that social capital is the ability to secure benefits via “participation in networks and other social structures” (Portes 1998, p. 6). Of course, the idea that interconnections favor individual upward mobility may also be found in writers like Mark Granovetter (1973, 1983) who avoid the term social capital.

While Bourdieu does not take an interest in whether the effects of social capital are positive or negative, in Coleman’s work, social capital is presented as exerting a fundamentally positive social influence, especially in the case of social problems tackled through the effectiveness of social capital. For Putnam too, social capital is a “blessing” that reduces anomie, promotes democracy, and produces wealth. However, Portes and his associates reject this all-positive account of social capital and its effects as one-dimensional, while stressing a number of negative aspects: Of prime importance is the exclusion of non-members, and the excessive demands made upon rich members of the social capital network (or group) for compliance, uncensored acceptance, and so forth.

Portes’s interventions offer a more balanced understanding of social capital and its potential. The notion is not rejected but rationalized, with emphasis on the need to systematically study the effects of social capital and avoid attributing irrelevant, accidental, or spurious effects to it (Portes 1998, 2000; Portes and Landolt 2000; Portes and Mooney 2002). This perception has led to conceptualizations of social capital more akin to the micro-level that focus on the individual’s relationships to her or his network of social connections and the benefits and resources she or he may muster. Such approaches tend to restrict the agentic impact, even if they give a place to it, while underlying that of social structure (Lin 2000, 2001). In such explorations, which tend to utilize qualitative methods, one of the main concerns is to decipher causality in generating and activating social capital (Mouw 2005; Smith 2003).

The wider promotion of the contentious notion of social capital, and the strengthening and broadening of its usage, mainly took place through the work of Putnam, who came to influence key politicians, including U.S. president Bill Clinton, plus a series of international organizations like the World Bank, the Organization for Economic Cooperation and Development (OECD), and the European Union. At the same time, social capital has come to be used in ever-increasing ways as a recipe for non-economic solutions to social problems (Halpern 2005). The overextension of its meaning and the consequent slackening of its application have led to contestation about its true content. It now appears that the notion of social capital has, to a significant extent, been taken over by agents of ideological and political intervention (Koniordos 2006). However, the social capital notion is certainly of social-scientific interest if its use is suitably restricted to what it may substantively explain.

Social Categorization

Social categorization—the collective definition and naming of categories of perceived phenomena—is fundamental to human cognition and culture. Given that it is so fundamental, it is not surprising to find that it has inspired a range of divergent social science approaches. These can be crudely divided into contrasting emphases on content or process.

To take content first, writing in 1903, Émile Durkheim and Marcel Mauss (1963) argued that social structures generate classificatory systems; culturally specific categorizations of the human body, animals, and the wider world, and the relationships between those categories, symbolize and rework relationships of opposition and alliance within and between groups. Later works in this structuralist vein, such as Claude Lévi-Strauss’s *Totemism* (1963), developed the notion that the natural world provides classificatory material that is “good to think with,” particularly about social relationships.

The basic axiom, that the social categorization of the world represents or dramatizes social structure, underlies Mary Douglas's anthropological discussions of cosmology, ritual, and symbolism (1966). Pierre Bourdieu took the idea further in analyzing modern French relationships between stratification, consumption, and categories of taste, style, and symbolic value (1984). Other authors, even though abandoning the structuralist underpinnings, have since explored similar territory (Lamont and Fournier 1992). The theme that the categories of culture are systematically related to social structure has inspired the academic fields of cultural studies and social studies of consumption.

Within social psychology, the study of social categorization has emphasized process. The most prominent contemporary theoretical school derives from Henri Tajfel’s “minimal group” experiments. These provided evidence that when people are arbitrarily placed in one of two groups in a laboratory setting, with no history of animosity and nothing at stake, intergroup negative discrimination results (1970). Reflecting the human need to create cognitive and social order, social categorization is, it is argued, sufficient in itself to generate identification of and with in- and out-groups. A large literature continues to develop and critique this paradigm (Brewer and Hewstone 2004, pp. 145–318).

Finally, another processual approach hinges upon the distinction, originally methodological, between “groups” and “categories”: The first is a human collectivity that is defined by and meaningful to its members, the second a collectivity that is defined from outside (during a census or survey, for example). This leads to a contrast between processes of group identification and of social categorization and the argument that identification is always a matter of internal self- or group identification, external categorization by others, and the relationship between the two (Jenkins 2004). Power—whose definition prevails—thus becomes central to our understanding of social categorization.

SOCIAL CHANGE
The concept of social change is central to the social sciences and, in particular, to sociology. The work of many of the pioneers of sociology, including the central triumvirate (Émile Durkheim [1858–1917], Max Weber [1864–1920], and Karl Marx [1818–1883]), involves a sustained reflection upon the changes they believed that they were witnessing in their societies and the new social forms they saw emerging (e.g., organic solidarity, modernity, bureaucracy, and industrial capitalism).

In certain respects change is an inherent feature of societies rather than a periodic event that they undergo or something extraneous that acts upon or happens to them. At whatever level one pitches the concept, a society is not a thing but a process. It comprises a vast web of interactions that unfold through time and, as such, is in a perpetual state of becoming. Any society is constantly in motion and, like the proverbial river, is therefore never quite the same from one moment to the next. The key question, from this point of view, is not why things change but why many social forms persist for as long as they do: that is, why and how they are reproduced. Nevertheless, forms do change, sometimes on a grand scale, and much social science is focused on the question of why this is so.

A key distinction can be found in classical and early modern social theories between revolutionary and evolutionary theories of change. This distinction hinges on the question of whether change happens in short dramatic bursts (revolutions) or more gradually, over the long term—the most likely answer being “both ways,” as the two modes are not mutually exclusive. Political revolutions, such as the French Revolution of 1789, are obvious exemplars for the revolutionary model, but we also refer to “the industrial revolution,” to “scientific revolutions,” and to such “cultural revolutions” as the Reformation or Enlightenment. Evolutionary change is more difficult to pinpoint because, by definition, it is gradual and occurs over long stretches of time, but it is easily revealed through comparisons of historically distant snapshots of social life.

Evolutionary theories often refer to interaction between the social form said to be evolving and its wider (social and/or natural) environment. Changing environments are said to “select” the forms that proliferate within them. This position can entail teleology; that is to say, it may rest upon an assumption, generally deemed erroneous by contemporary social theorists, that social forms serve a purpose within the wider systems to which they belong and, more problematically, come into being because they serve that purpose. Functionalist accounts, when not criticized on the grounds that they cannot explain change, are often criticized for making such assumptions. Evolutionary accounts are not necessarily teleological, however, even when they work with the notion of environmental fit. Darwin’s theory of evolution by natural selection, for example, is non-teleological. Biological “adaptations” do not emerge because they fit with the environment, in Darwin’s view. Their emergence is purely contingent—though they “die out” if they do not fit with their environment or lose out to better-fitting “adaptations” in the struggle for survival. Moreover, insofar as evolutionary accounts do rest upon teleological assumptions, this does not serve to distinguish them from revolutionary accounts, which can be equally prone to teleology. Not only, for example, do some variants of revolutionary Marxism adopt functionalist explanations, some also adhere to the teleological notion that history is propelled in the direction of a pre-given endpoint and thus revolution is inevitable. Furthermore, the “laws” of social change, which are said to propel society in a particular direction and which one finds in some Marxist accounts, while not necessarily teleological, are problematic on account of what Karl Popper calls their “historicism.” Popper’s critique of historicism (1969) defies brief summation. Suffice it to say, however, that he is critical of the claims of some Marxists to have discovered “iron” laws of historical necessity and change because, he argues, our knowledge of these laws inevitably changes our behavior and thereby changes the course of history itself, such that the “laws” could not have been “laws” in the first place. In part this is a claim about the role of knowledge and ideas
in steering the course of change and a critique of materialist theories that ignore or deny their role. More profoundly, however, it is a claim about the role of reflexivity in history. We are not condemned to follow a particular historical trajectory, according to Popper, because we have the capacity to reflect upon the flow of history and this affords us the opportunity to act differently than we would otherwise have done.

Both revolutionary and evolutionary accounts of social change have come under attack in recent social science, particularly in the context of “postmodern” and “poststructuralist” theories. In addition to challenging “grand narratives” of history (i.e., accounts that purport to tell the story of human history in toto and in the singular), these theories have challenged the notion of progress that, they argue, underpins such narratives. In part this critique has been informed by a dissatisfaction with the ethnocentric assumptions built into many accounts of progress; that is, the tendency for writers to treat their own society and standpoint as the furthest point hitherto achieved by any society along a continuum that all societies can be measured against. At a deeper level it is informed by a suspicion of all forms of evaluative discourse, centered ultimately on claims regarding the impossibility of arriving at an unprejudiced or rational basis by which to establish criteria of evaluation.

The more extreme claims of postmodernists can be challenged by reference to the pragmatic possibility of deriving local and specific criteria by which to evaluate change: For example, if we are prepared to agree that reducing infant mortality is a good thing, then we can argue that Western societies, insofar as their rates have reduced, have progressed in this respect. We do not need to establish a universal standard against which all societies should be measured or, conversely, to eliminate the value judgment that something is a “good thing” in order to make meaningful claims about progress, as long as we can derive mutually agreeable criteria upon which to base our assessment. However, much contemporary debate on change is framed in postmodern terms. Whereas classical social theory was centered on the emergence of modern society, contemporary social theory is centered on the transition to postmodern society. Paradoxically, postmodernism has become something of a “grand narrative” of history, and a dominant one at that.

SOCIAL COGNITION

Social cognition is the branch of social psychology that studies how people think about themselves and other people. It focuses on the steps people take and the conclusions they reach as they strive to make sense of their social environment. The field tends to view people as information processors, something like a computer, who take in information from the outside world, sort that information out and interpret it, calculate a judgment, and then choose a behavior in response. In doing so, the field examines what information people pay attention to, how they analyze it, how they reach judgments based on that information, how those judgments guide their behaviors, and then which parts of the information they remember.

Work in social cognition is wide-ranging and explores a breathtaking diversity of topics. For example, some social cognitive researchers investigate how people develop opinions and attitudes about social issues. Others examine whether people’s judgments of others are distorted by stereotypes. Others look at whether people reach decisions that are wise and rational versus faulty and costly. Others study how people reach impressions of themselves that lead to high versus low self-esteem.

Social cognition principles carry a wide variety of implications for real world pursuits. Social cognition principles, for example, explain why people make right versus wrong decisions about their health. It suggests the best ways to teach students to remember school material. It
explains the pitfalls that prevent people in negotiations from reaching harmonious settlements. It explains how people can commit discrimination against people from other ethnic or social groups without even knowing it. It describes why and when people make poor decisions about their money.

One can claim that social cognition has always been a featured part of social psychology, even when the rest of psychology has neglected, or even denied, the importance of people’s internal thought processes. In particular, in the early to mid-twentieth century, the bulk of psychology was dominated by the behaviorist tradition, led by B. F. Skinner (1904–1990) and others, which emphasized how organisms reacted to rewards and punishments while studiously avoiding any talk of that organism’s internal psychological world. During this era, many social psychologists squarely examined that internal life, exploring how people developed their attitudes toward social issues, as well as how they formed stereotypes about social groups, or made attributions about the causes of other people’s behavior.

However, in the 1960s, with the advent of the cognitive revolution, things changed dramatically. The mainstream of psychology became fascinated with the organism’s internal life—how that organism perceived, thought about, and remembered the world around it. Cognitive psychologists, in particular, generated many sophisticated and powerful theories describing thought and memory. Social psychologists quickly adopted these theories and methods to explore in finer detail how people strive to comprehend events in their social world. Today, work on social cognition remains a vigorous and prominent branch of social psychology.

Although work in social cognition is too diverse to be captured in a simple catalogue, one can point to dominant ideas and themes that social cognitive research has repeatedly demonstrated.

**SCHEMATA: THE BUILDING BLOCKS OF SOCIAL COGNITION**

One prominent theme focuses on the building blocks of people’s thoughts. People carry with them information about individuals, social groups, objects, and events arranged in schemata (singular: schema). A schema is a knowledge structure containing the features and examples associated with a person, group, object, or event. For example, people’s schema of bird usually contains such characteristics as wings, feathers, a beak, and flight, as well as some common examples of birds, such as robin and duck. Usually schemata are described as associative networks, that is, as a web of linked associations. Thus, when the concept of bird comes to mind, these associative links activate the relevant features and examples (e.g., wings, duck) connected to the concept, thus also bringing those notions to mind.

Schemata are tremendously helpful for social life. If a friend tells you, for example, that he or she went to a restaurant last night, you can easily surmise, because you possess a special type of schema for an event called a script, that the person looked at a menu, ordered food, ate it, paid the bill, and left a tip. Your friend does not need to specify these details; you already know.

That said, schemata can also be misleading or harmful, especially when people try to recall the past. For example, if someone asks George to remember the words drowsy, bed, pillow, snoring, and nighttime, he will probably remember most of these words. But he will also probably mistakenly recall the word sleep because all those terms listed above are linked to sleep through the associative network (the schema) of this concept. Memory errors prompted by schemata can be quite profound. For example, people witnessing a crime may misremember that the culprit had a gun, a disguise, or unkempt hair if it fits their schema of the event they witnessed. Schemata also explain how stereotypes can distort memory. If, for example, a friend describes a professor as distant, smart, and assertive, one might also mistakenly recall that the friend said the professor was arrogant—if that attribute fits one’s schema of a professor.

The impact of schemata on social judgment, interpretation, and memory has been shown to be profound in a wide array of studies, and there has been a good deal of discussion about the specific form that schemata take. According to the prototype view, schemata consist of the features associated with an object or event (such as wings and feathers to a bird). According to an exemplar view, schemata consist of typical examples of a concept (such as a robin being a typical example of a bird). Research ultimately suggests, however, that schemata tend to be a blend of both features and examples.

**ERRORS AND BIASES IN SOCIAL JUDGMENT**

One additional prominent theme in social cognitive research scrutinizes cognitive habits that lead people to make errors and biases in their judgments. For example, one such consequential habit is confirmation bias. Research on this bias shows that when people ask a question (e.g., “Is Jerry outgoing?”), they tend to look for information that would confirm the question in the positive (e.g., “He does go to parties”) and not for information that would disconfirm it (e.g., “He said last week he hated talking in front of large groups”). When the opposite question is asked (e.g., “Is Jerry shy?”), people instead search for information that would confirm that reverse hypothesis, leading to very different conclusions.
Confirmation bias can lead to several problems in judgment. For example, it can lead people to be overconfident in their predictions about themselves and others. When people consider a question soliciting a prediction (e.g., “Will I get a good grade in this class?”), they tend to consider information that suggests that the answer is “yes.” This can lead them to overconfidence about the chance that their prediction will prove to be accurate. That is, they may say that they are 90 percent sure their prediction will be correct even when the real chance is closer to 70 percent. Indeed, when people say they are 100 percent certain of their prediction, they tend to be wrong roughly one time out of five. Some researchers have suggested that a valuable habit for avoiding overconfidence is to also ask how an event might go in the opposite direction from that posed in the question (e.g., ask the reasons why one might get a poor grade). This consider-the-opposite strategy has been shown to reduce overconfidence in people’s predictions.

People also suffer from illusory correlations, seeing relationships between variables even when they do not exist. Some illusory correlations are inspired by schemata and stereotypes. For example, in an experiment described in a 1967 article, Loren J. Chapman and Jean P. Chapman showed participants a series of drawings, some of which were purportedly drawn by people suffering from paranoia. Participants in the study tended to conclude that the drawings of paranoid individuals more often than not included people with larger eyes—even when there was no relationship between eye size and mental illness in the drawings they looked over.

Other illusory correlations are inspired by what people find easier to remember. For example, people tend to remember unusual behaviors (e.g., riding a unicycle) performed by rare groups (e.g., Alaskans), as reported by David L. Hamilton and Robert K. Gifford in a 1976 article. Thus, when asked if there is any relation between a rare behavior and a rare group (e.g., do Alaskans participate in odd sports?), people report that such a relationship exists, even if the evidence they have reviewed fails to support this conclusion. Because rare-rare combinations are memorable, they lead to illusory correlations.

People also fall prey to the fundamental attribution error (also known as the correspondence bias), which means that they give too much weight to a person’s personality in explaining, evaluating, and predicting social behavior and too little weight to situational forces. That is, people look primarily to a person’s internal character to explain his or her actions, and not to factors outside the person that could have produced the behavior. This bias most commonly arises when people make attributions for another person’s behavior; that is, they try to identify the causes for why the behavior occurred. For example, if you say that “John stumbled while learning the dance,” people tend to leap to the conclusion that John is clumsy (i.e., something about his internal personality) rather than that the dance was difficult (e.g., something about the outside situation).

Several studies have provided powerful demonstrations of the fundamental attribution error. Consider the classic Milgram experiment, completed in the 1960s, in which Stanley Milgram (1933–1984) demonstrated that a majority of participants, if asked, would continue to shock another participant if an authority figure asked them to—even if the other participant suffered heart problems and had stopped answering, and for all practical purposes might be dead. Almost everyone who hears about the study denies that they would “go all the way,” complying with the experimenter until the session is curtailed. However, up to two-thirds of people in this situation do go all the way. The situation is extremely powerful even though people do not see it, and there are few indicators from a person’s personality that reliably predict whether that person will comply or defy the command to shock another person who has stopped answering.

People also make errors because they rely on quick heuristics to reach their judgments, according to the work of Amos Tversky (1937–1996) and Daniel Kahneman. One such example is the availability heuristic, in which people judge the odds, frequency, or truthfulness of an event based on how quickly examples of it spring to mind. For example, if one asks how commonly words of the form ——n- appear in English, people tend to say that there are not many. However, if asked how many words of the form ——ing appear, people say quite a few, mostly because such words are easily brought to mind. Of course, all ——ing words are also ——n- words, so the latter type of word, paradoxically, must be more frequent.

People also rely on the representativeness heuristic. This heuristic refers to the fact that people judge the odds, frequency, or truthfulness of an event based on how well it matches a schema in their head. For example, suppose you were told that Linda is politically liberal and a philosophy major. Which of the following descriptions do you think is the most likely to be true and which the least: that Linda is a feminist, that she is a bank teller, or that she is both a feminist and a bank teller. Most people rate “feminist” as most likely and “bank teller” as least, although that is necessarily an error. Mathematically, the least likely event must be that Linda is both a feminist and a bank teller. Why? If Linda is both, then she is already a bank teller—and there is an added chance that she might be a bank teller without being a feminist. Thus, the single description of “bank teller” must be more probable than being both a teller and a feminist.

This conjunction fallacy (i.e., rating a combination of two events as more likely than one of its two individual
component events) is caused by the representativeness heuristic. People form a schema of Linda and then quickly compare the various events (e.g., is a bank teller) to this stereotype. If the event matches the schema (e.g., is a feminist), it is seen as probable. If it does not (e.g., is a bank teller), it is seen as improbable. However, in using this heuristic, people commonly violate the simple mathematics inherent in the situation, and thus reach conclusions that cannot be right.

In the following heuristics, people also ignore other valuable information that would lead them to more accurate predictions. For example, people tend to neglect the base rates of events, even though these rates have a large impact on what will happen. Base rates refer to the commonness of an event. A high base rate means an event is common (e.g., people tend to have ten toes); a low base rate means that an event is rare (e.g., people tend not to have more than ten toes, although some do). The overall base rate of an event is a valuable indicator about whether or not it will occur in the future, but people, relying on availability and representativeness heuristics, tend not to factor base rates into their judgments and predictions. For example, let’s say that you know someone who is over seven feet tall and athletic. Is he more likely to be an NBA basketball player or an accountant? Most people quickly predict that this person is an NBA player, because that fits their schema of a professional basketball player (the representativeness heuristic at work), but they should actually predict that he is an accountant, because accountants far outnumber NBA basketball players. That is, the base rate of accountants is several times higher than the base rate of being an NBA basketball player. Because being an accountant is the much more common event, it is the event one should predict.

DUAL SYSTEMS IN SOCIAL THOUGHT

In another predominant theme, social cognitive work has also increasingly recognized that people possess two very different modes of thought. System 1 is a rapid mode of thought, in which people reach their judgments quickly through simple associations and heuristics, like the availability heuristic. System 2 is slower, conscious, deliberate, effortful, rule-based, and analytical.

Anyone who has solved a complex math problem is familiar with system 2. This is the system in which people consciously apply rules to compute some sort of judgment. People may not be as familiar with the operation of system 1. Indeed, at its extreme, system 1 may work so rapidly that a person is not even aware of its operation.

System 1 thinking is often associated with being automatic. There are many senses in which thought can be automatic. First, automatic thought can be quick. For example, people recognize the faces of their friends and family in an instant, without conscious deliberation. Second, automatic thought can be efficient, in that it does not detract from other tasks that people apply themselves to. For example, people can drive a car along a familiar route while fully engaged in other tasks, such as listening to the car stereo or talking to a passenger. Third, automatic thought can be completed without monitoring. People can form perfectly grammatical sentences, for example, without consciously monitoring the construction of each single phrase. Fourth, automatic can mean that the thought is outside of the control of the individual—that it just happens. Indeed, it often requires no conscious goal to set itself in motion. For example, few Americans can hear the date “September 11” without reflexively thinking of terrorism.

Finally, and perhaps most importantly, automatic thought can occur without one being aware of it. When this occurs, the thought is usually described as unconscious (i.e., below awareness) or preconscious (i.e., occurring before any thought reaches consciousness). Ultimately, this means that the conclusions people reach can be shaped by influences they are not aware of.

These influences are most directly shown in studies of priming, in which people are exposed to incidental material that later shapes their conclusions about some seemingly irrelevant situation. For example, if people complete a sentence-completion task that contains such words as hostile, mean, and unfriendly, they will judge a person they encounter soon afterward as more unpleasant and aggressive than they would if exposed to the words kind, generous, and sociable. The influence of priming can occur even when people are not aware of the prime. For example, John A. Bargh, Mark Chen, and Lara Burrows (1996) exposed college students to words associated with elderly people (e.g., wisdom, Florida) so quickly that the students were not aware that they had been shown any words at all. They thought they were merely seeing flashes on a computer screen. Despite this fact, as students left the experiment, exposure to these primes caused them to walk more slowly (a stereotypical attribute of the elderly) to the elevator as they left the experiment.

System 1, and the automatic thoughts that come with it, produces wide-ranging consequences. For example, the accuracy of people’s judgments, as described above, is heavily influenced by rapid use of availability and representativeness heuristics. Some forms of system 1 thinking can also be shown to trump system 2 thought. Norbert Schwarz and colleagues in a 1991 article showed how system 1 elements can have more influence than the actual content of conscious thoughts. In one study, they asked college students to write down six examples of their own assertive behavior. Students found this task easy. Another
group was asked to write down twelve examples and found this task difficult. Later, when asked to rate their assertiveness, the first group saw themselves as more assertive than the second group—even though the second group had generated a greater number of examples indicating that they were assertive. Schwarz and colleagues argued that the first group had perceived themselves as more assertive because they were relying on the availability heuristic. Generating six examples was so easy and available that it tended to convince students that they were assertive. System 1 (the availability heuristic) in this case was a more powerful influence than system 2 (the actual number of examples in conscious thought).

The impact of system 1 thought is also evident in social attribution. People appear to reach attributions about others quickly and spontaneously, through system 1, even without a conscious goal of trying to understand those people. For example, if you mention that Janice helped the elderly woman carry her groceries to the car, many people will rapidly and unknowingly classify the behavior as helpful. (There is an ongoing debate about whether people think of the behavior or the person, Janice, as helpful.) Indeed, if cued with the word helpful later, people will be more likely to remember the sentence that inspired the thought.

Such spontaneous system 1 attributions may explain the fundamental attribution error. Daniel T. Gilbert and colleagues (1988) have proposed that people make rapid attributions to another person’s personality. Once made, people correct these quick personal attributions by considering the impact of the situation in a more effortful, conscious, system 2 way. In support of this idea, Gilbert and colleagues have shown that people make greater attributions to someone’s personality if they are distracted by some other task, because they are deprived of the cognitive capacity necessary to correct for the quick personal attributions produced by system 1.

System 1 also carries consequences for stereotyping. Patricia G. Devine (1989) has suggested that people apply stereotypes in their judgments of others in a quick, system 1 way. Importantly, these stereotype-inspired thoughts even occur to those who wish not to be influenced by them. People who consciously deny stereotypes based on gender, race, or age know that those stereotypes exist and what they are—and these stereotypes will produce automatic, system 1 associations even among these people. In response, those who wish to avoid using stereotypes must apply more effortful system 2 thought to correct for the impact of those stereotypes. However, when people do not have the cognitive capacity to perform this system 2 correction, they will commit stereotypical thinking even though they wish to prevent it. This may happen when they are tired or distracted by some other task.

System 1 also influences attitudes and persuasion. As Shelly Chaiken and Yaacov Trope (1999) have pointed out, people can be persuaded to hold an attitude via two different routes. Through a heuristic route, people can be persuaded in a system 1 way through rapid associations and rules of thumb. For example, people can be persuaded of a viewpoint if the person trying to persuade them is physically attractive, or has an impressive title, or just rattles off a large number of arguments. This type of persuasion occurs when people are not motivated to think deeply about what they are being told. However, when people are motivated, they more effortfully and consciously deliberate over what they are told. This is the systematic route to persuasion, and depends on whether people find the arguments they are given to be strong. (John T. Cacioppo and Richard Petty’s elaboration likelihood model offers a similar treatment of system 1 and 2 routes to persuasion).

**Implicit versus Explicit Attitudes**

The presence of system 1 also means that people may hold multiple, and sometimes contradictory, attitudes about social groups and issues. For example, at a conscious, explicit level, people may harbor no negative attitudes toward people from other racial groups, or the elderly, or the political party opposite their own. However, at an implicit level, below conscious awareness or control, people may hold such prejudices. That is, they may hold automatic negative associations to those groups that they are not aware they have.

Much research has shown how attitudes at the implicit level may differ from those at an explicit level. For example, people tend to deny explicitly having any negative opinions of racial groups different from their own. However, if placed in a performance task that assesses their automatic, implicit associations, such negative links are often found. For example, in one version of the implicit association task, people are asked to complete two tasks simultaneously. In one task, they are asked whether a face is of a European American or an African American, pressing a button with their left hand if the face is European and with their right if the face is African. Intermixed with this task, they are also shown words (e.g., puppy, disease) and asked if each is positive or negative in nature, using their left hand to indicate the former and their right the latter. They then perform these two intermixed tasks again, but this time the hands indicating positive and negative words are switched.

Most European Americans find this second version of the task to be more difficult, in that they are using the same hand to indicate European and negative (an association they may not have at the automatic level) and the
other hand to indicate *African* and *positive* (again, an association they may not possess at the automatic level). African American participants find the second version of the task to be easier than the first, presumably because it matches associations (e.g., *African* and *positive*) that they possess at an implicit level.

**NEW DIRECTIONS**

Work in social cognition has moved vigorously in several directions since 1990. For example, all the work described so far paints social perceivers as cold, machinelike calculators, calmly using systems 1 and 2 to determine some judgment about their social worlds. More recent work since the 1990s has recognized that cognition need not only be “cold,” it can also be “hot,” involving vivid and full-blooded emotions. Thus, recent work in social cognition increasingly focuses on the role of emotions in social thought. For example, research has shown that emotional arousal prompts people to pay attention more to the evaluative charge of information in their environment—that is, to whether it is positive or negative—over other aspects of that information. Fear and anxiety also narrow attention to central and salient aspects of a situation, at the expense of more peripheral features.

Emotions also lead people to make different assumptions about a situation. When people become fearful, for example, they perceive themselves to lack control over a situation. Thus, they become more pessimistic and reluctant to take on risks. However, when people are angry, they perceive themselves as more in control and more likely to seek risks out. This was directly shown in a survey taken after the terrorist attacks in the United States on September 11, 2001. Those asked first to describe how the attacks made them fearful perceived the United States to be more at risk for future attacks than did those asked to describe how the attacks made them angry.

Work in social cognition since 1990 has also begun to explore the role played by culture, taking pains to study how social cognition operates around the world. In doing so, researchers have found that culture has a profound impact on the ways people think about their social world and the conclusions they then reach. Differences in culture also appear to extend even to perception of the physical world. For example, if people are shown a scene, North Americans are more likely to describe and remember central components of the scene. East Asian respondents, relative to their North American counterparts, are more likely to describe and remember the context surrounding those central components, better recalling peripheral details of a scene.

This different degree of attention paid to the center versus the context is echoed in social judgment. People from East Asia also tend to avoid the fundamental attribution error, more frequently emphasizing situational factors that may have produced a person’s behavior, in contrast to what is emphasized by their North American counterparts. In essence, people from East Asia tend to emphasize the surrounding situational context in their explanations for the behavior of other people, whereas North Americans tend to emphasize the central actor.

Finally, social cognition research since 2000 has increasingly delved into the neurophysiology of social thought, examining the brain structures that support judgments and decision making. By using such techniques as fMRI (functional magnetic resonance imaging) or ERP (event-related brain potentials), psychologists can determine which neural structures in the brain are active as people reach decisions. For example, people who possess negative implicit attitudes toward ethnic groups different from their own (as measured by the implicit association test described above) show more activation of the amygdala, a part of the brain associated with emotional learning and evaluation.

Studies of this type have also begun to map different neural routes that people take to reach conclusions about their social world. In a study on moral judgment by Joshua D. Greene and colleagues (2001), participants were asked how they would respond to the following two moral dilemmas. One dilemma concerned whether participants would switch the track that a train was traveling on to keep it from hitting and killing five people, knowing that the train on its new track would unfortunately kill one other individual. The second dilemma concerned whether participants would push a person in front of a train, killing him, in order to stop the train from killing five people further down the tracks. Although the two scenarios share the same overall structure (i.e., sacrificing one person to save five), people tend to reach different decisions about how to act, being more likely to switch the train track in the first scenario than to push the person onto the tracks in the second.

Participants also tend to reach these decisions via different neural routes. Participants in this study appeared to solve the first dilemma in a calculated system 2 way, analyzing the benefit of switching the train track. In support of this observation, fMRI measurements suggest that as people considered the scenario their parietal lobes, as well as the right middle-front gyrus, were active—areas associated with the “working memory” people use as they think through a decision. In contrast, people appeared to solve the second dilemma by going with their initial emotional reaction, with brain areas associated with emotion (e.g., the right and left angular gyrus, the bilateral posterior cingulate gyrus, and the bilateral medical frontal gyrus) being most active.
CONCLUDING REMARKS
Social cognition is a vibrant area of research. Its influence is also increasingly felt in other scientific and professional disciplines, as scholars in medicine, law, business, education, and philosophy comb its insights to provide knowledge to address questions in those areas of endeavor. In a sense, this vibrancy should not come as a surprise. Every day, people expend a great deal of effort in social cognition, trying to make sense of themselves and the people around them. It is a safe bet that they will never find a point in their lifetime when they can stop doing this task. If this is true of people in everyday life, then it must also be true of the social cognition researcher, who, after all, is also just trying to make sense of what other people do.

SOCIAL COGNITIVE MAP
In their 1985 study Robert B. Cairns, Jane E. Perrin, and Beverly D. Cairns defined the Social Cognitive Map (SCM) procedure as a peer-report method for identifying social groups of children or adolescents in school settings. The SCM procedure, originated by developmental psychologist Robert Cairns, involves three distinct steps: collecting peer reports of social groups, aggregating those peer reports in a single matrix, and analyzing similarity patterns in the matrix to identify peer groups.

To collect peer reports of groups, each participating youth is asked: “Are there any kids here (at your school/in your classroom) who hang around together a lot?” The question can be posed during an individual interview or with a group administered questionnaire. In either case respondents are encouraged to identify each member of as many groups as they can recall. Sometimes a roster of peers in the setting is provided to facilitate recall, but respondents are never required to classify all peers into groups. Each respondent’s report can be considered the individual’s “social cognitive map” of the setting. These individual social cognitive maps are aggregated into a symmetric matrix containing one row and one column for each individual in the setting, regardless of whether or not the individual provided a report of groups. Off-diagonal cells summarize conominations: For example, the total number of times that individuals i and j were named to the same group is placed in cell cij. Each cell along the diagonal (e.g., cii) contains the total number of times that an individual was named to any group. Algorithms are applied to the conomination matrix to identify dyads that interact more than one would expect by chance or to identify peer groups. Developmental psychologists typically have identified groups based on similarity in conomination patterns.
Social Comparison

(e.g., intercorrelating the columns of the conomination matrix, then using decision-rules or standard data reduction procedures to identify group structures), but software developed for social network analysis provides a wide range of alternative group-detection algorithms.

The SCM procedure is based on two assumptions: first that there is some degree of consensus among youth regarding peer affiliation patterns, and second that youth are expert participant-observers in peer social networks whose reports have some connection to observable interaction patterns. These assumptions have been validated in several empirical studies. For example, conomination matrices routinely reveal greater than chance levels of agreement among peer respondents; and observational studies document that youth interact with members of their SCM-identified peer groups at rates three to four times higher than with other same-sex classmates.

The SCM procedure focuses on identifying relational ties linking individuals in a setting, which distinguishes it from widely used peer-report methods that focus on measuring the status or behavior of individuals (Cairns 1983). For example aggregating respondents’ reports of peers whom they “like most” and “like least” yields powerful measures of peer acceptance and rejection, respectively; and aggregating respondents’ nominations of peers who match specific behavioral descriptors (e.g., “starts fights”) provides robust measures of aggression. It is possible to derive individual-level measures from the SCM conomination matrix, but the SCM procedure’s most unique feature is its explicit focus on relational ties and structures.

Among methods for assessing relational ties among peers, the advantages and disadvantages of the SCM procedure are best understood in the context of alternative procedures. Direct observations have face validity and can produce dense interaction matrices for analysis, but they are costly to gather and may be impractical among older youth because researchers typically lose access to important settings for peer interaction. Self-reported friendships or social groups provide unique information on subjectively valued relationships, but they are vulnerable to self-enhancement biases and result in missing data when individuals decline to participate. There is little data documenting the validity of teacher and parent reports of youths’ school-based peer relationships.

In this context the SCM approach has several notable strengths: The necessary data is relatively inexpensive to collect; the multi-informant method produces dense conomination matrices that provide a robust basis for applying a wide range of social network analysis tools (Gest, Moody, and Rulison 2007); and the resulting peer group structures capture reliable and valid patterns of relational ties among all members of the network, even those who do not provide individual reports.

SOCIAL COMPARISON

A simple but powerful insight about how people evaluate themselves is that these evaluations often result from comparisons with others. How do people know if they can run fast? Do they run around a track and simply examine their times? No, they compare their times with that of others. How do people know if their opinions are correct? Is there an objective standard to which they can turn? No, people are likely to consult the views of those around them and conform to the majority view.

A THEORY OF SOCIAL COMPARISON PROCESSES

Although an age-old idea and variously found as a building block for many theories of social behavior across disciplines, this insight was first systematically thought through by the social psychologist Leon Festinger in his now classic 1954 paper, “A Theory of Social Comparison Processes.” Festinger pointed out that most judgments about the self, in the absence of objective criteria, must be based on social comparisons. In fact, he claimed that this lack of objective criteria was the typical state of affairs, leading to the conclusion that much of what people infer about themselves has relativistic roots.

Festinger also posited a human drive to self-evaluate because accurate self-evaluation should be adaptive. It was to the human organism’s benefit to know its abilities accurately and to assess the prevailing attitudes of others.

Another claim of the theory was that similar others are sought for self-evaluation because they are most useful
for accurate self-evaluation. More precisely, people prefer comparisons with others who are similar on attributes that are relevant for the comparison. A male high school student would not compare his running time with that of an inexperienced, female middle school student. He would use the running times of other male runners of similar age and training. Likewise, with regard to opinions, people seek out and usually conform to the opinion of people with whom they share important group characteristics.

Festinger's claim for the adaptive implications of seeking social comparisons fits well with evolutionary psychology. Ranking on various characteristics often determines survival and access to resources that lead to reproductive success. Human beings, by this logic, should be highly attuned to social comparisons and the variations in rank that they reveal.

ADVANCES IN SOCIAL COMPARISON THEORY

Social comparison theory has evolved in a number of directions. Philip Brickman and Ronnie J. Bulman (1977) pointed out that the potentially weighty implications for the self resulting from social comparisons mean that these comparisons can produce both pain and pleasure. Upward social comparisons, with individuals who are superior to oneself, can often undermine feelings of self-worth. Such social comparisons might often be avoided as much as sought. Downward social comparisons, with individuals who are inferior to oneself, may bolster feelings of self-worth. Social comparisons of this sort may be sought and savored. Thus, because of either their self-threatening or bolstering effects, social comparisons may serve as much to protect or enhance the self as to further accurate self-evaluation.

Brickman and Bulman focused largely on the pain of inferiority and the pleasures of superiority, but more recent thinking emphasizes that people are quite capable of having either positive or negative reactions to both upward and downward social comparisons. One might suppose that upward comparisons would typically lead to contrast effects, that is, the conclusion of relative inferiority. But partly because of robust judgmental biases allowing individuals to construe themselves as better than they are, an upward comparison can actually boost self-evaluation. In this sense, people assimilate toward the social comparison target, enhancing self-views. Also, one might think that downward comparisons would typically lead to contrast effects and the conclusion of relative superiority. But, downward comparisons, despite self-serving biases, can also produce assimilation effects. This might occur when another person's inferior status suggests a similar fate for oneself, producing anxiety rather than a pleasing sense of superiority.

What determines assimilation versus contrast? Perceptions of control seem to be especially important. In the case of upward social comparisons, if people believe that another's superiority suggests something attainable, then pleasing assimilative reactions can occur. If the superiority suggests an unattainable goal, however, then displeasing contrastive reactions should result. Thus, a freshman might look at the success of a senior as hopeful indication of what he or she might end up achieving; but an underachieving fellow senior might experience this comparison in a depressive, contrastive fashion. Indeed, one way of suggesting how much social comparisons influence everyday life is to note the many emotions that people feel as a result of social comparisons, depending on whether the comparisons are upward or downward, contrastive or assimilative. Upward comparisons, when they produce contrastive effects can lead to the painful, often hostile emotions of envy, resentment, or shame. When they are assimilative in nature, they can lead to the pleasurable, beneficent emotions of admiration and inspiration. Downward comparisons, when contrastive, can produce such emotions as pride and contempt; when they are assimilative, they can produce worry, fear, or pity.

Social comparison processes continue to find a central place in many efforts to explain social behavior. One example is the vast amount of influential research inspired by social identity theory (Tajfel and Turner 1979), which assumes that a large part of a person's identity follows from social comparisons between in-group and out-group. Another example is the research on social norms and social influence (Blanton and Christie 2003). Yet another example is the extensive, developing literature on the implications of social comparison for subjective well-being and health (Buunk and Gibbons 1997).

Research and theorizing on social comparison processes continue unabated. Festinger's claims about why and how social comparisons influence people's self-evaluations has received considerable support and has moved far beyond its original scope. There is little doubt about the pervasive and foundational role of social comparisons in determining self-evaluations, in influencing people's behavior, and in shaping people's understanding of their experiences.

Social Constructionism

Richard H. Smith

SOCIAL CONSTRUCTIONISM

The process of creating social reality by individuals, groups, or organizations in interaction with social structure is often termed social construction. Sociologist W. I. Thomas defined the concept of the situation as, “If men define situations as real, they are real in their consequences” (Thomas and Thomas 1928, p. 572). And this theorem demonstrates that human perceptions in large and small ways create the social world.

While individuals actively participate in creating social reality, simultaneously, they are influenced by social reality. Human behaviors, everyday interactions, and social life do not occur in random fashion; rather daily experiences in the social world are patterned based on the organizing of individuals, groups, and organizations. As Peter Berger and Thomas Luckman presented, “Society is a human product. Society is an objective reality. Man is a social product” (Berger and Luckman 1966, p. 61).

Different perspectives and research approaches are used to investigate social construction and its results. Social scientists have used the term social construction to emphasize how identity, roles, statuses, knowledge, and institutions are created and maintained relating with other members of society in socio-historical context. Postmodern theorists demonstrate how social reality is constructed by deconstructing in various ways what is taken as reality. For instance, some postmodern researchers deconstruct knowledge to demonstrate a totalizing general theory or an ultimate truth is misguided.

The creation of identity, the sense of self, demonstrates how the social construction works at the individual level, how significant it is to an individual in various contexts, and how individual identity creation is a reflection of social structure. Individual identity is formed by social processes in different socio-historical contexts. So identity can be fluid, situated, multidimensional, and interactive between individual consciousness and social structure. Identity is created, re-created, and maintained by reacting upon the given social structure and personal characteristics.

Social psychological studies have focused on how social structure intersects with individuals’ construction of identity. Many studies focus on people experiencing identity struggles, especially managing lower status in the hierarchical order of social life. For example, creation of sexual identity in relation to majority culture is complicated and is a particular struggle for those belonging to marginalized or stigmatized groups, such as homosexuals. It is through interacting with others and by learning cultural norms and values that individuals become aware of which sexual identity is desirable and appropriate in society. Thus, for homosexuals, construction and maintaining of their sexual identity is the socio-political process of obtaining legitimacy.

Social scientists have incorporated various types of research methods to explore the process and consequence of social construction. These include in-depth interviews, participant observation, ethnomethodology, documental-historical studies, discourse analysis, experiments, and surveys.

SOCIAL CONSTRUCTS

Social constructs or social constructions define meanings, notions, or connotations that are assigned to objects and events in the environment and to people’s notions of their relationships to and interactions with these objects. In the domain of social constructionist thought, a social construct is an idea or notion that appears to be natural and obvious to people who accept it but may or may not rep-
resent reality, so it remains largely an invention or artifice of a given society.

Games are an example of socially constructed entities and often exist because of certain sets of conventional rules. These sets of social conventions and agreement to abide by them give games their meaning in any given social context. The game of football could be played in any way, but there have developed over the years known conventional rules governing the players, spectators, and the game’s organization. The meaning given to games is therefore socially constructed.

Gender, which represents ways of talking, describing, or perceiving men and women, is also a socially constructed entity. Generally distinguished from sex (which is biological), notions of gender represent attempts by society, through the socialization process, to construct masculine or feminine identities and corresponding masculine or feminine gender roles for a child based on physical appearance and genitalia.

Social class is yet another socially constructed entity. While most scholars agree that class appears to represent a universal phenomenon, its meaning is often contextually located because what determines class varies from one society to another, and even within a culture different people may likely have different notions of class determinants.

Depending on the constructionist perspective, social construction may be the outcome of human choices rather than of immutable laws of nature. Here, then, lies the core issue over which social scientists diverge. Are human ideas and conceptions generated more on subjective criteria than on objective realities? Debates have raged in the social sciences along the divide of science versus objective truth. In the social construction of reality, the question has often been asked: To what extent is our claim to knowledge supported by reality? In other words, to what extent is this claim a social construct? Some writers believe that to the extent that knowledge is aligned with reality, it approximates objective truth; anything less represents a social construct. According to this thinking, even morality is a social construct. However, others believe that all knowledge is social construction.

The basis of this debate—in fact the point of departure among scholars—is the claim that social constructions are based on social facts and surrounding social conventions. Thus constructions based on “facts”—facts that are not ontologically dependent on the social structures and conventions of society—are not. However, Ian Hacking (1999) believes that there are few if any “universal constructionists,” in which case few people would argue that the sun or DNA are socially constructed, existing entirely independently of that construction. On the contrary, the social arena is quite different, as vital social realities are socially constructed, existing by virtue of that social construction by people over time and space. This seeming narrow threshold between scientific construction and social constructs presents problems in social analysis—indeed hard nuts that need to be cracked and cracked satisfactorily.

In the resulting ongoing science wars, one side argues that scientific results, including even those of basic physics, are socially constructed. Others protest, arguing that these results are usually discoveries about our world; they are not the production of society but exist independently of consciousness. However, some sociologists, such as Barry Barnes and David Bloor (1982), have taken a relativist view of social construction, claiming that any notion is as good as the other. Thus, for instance, if a new social construction of the Holocaust emerges, arguing that claims about Nazi extermination camps are exaggerated and that the gas chambers are a fiction, that view may well then be at par with other beliefs about the same phenomena, though this may represent historical revisionism. Nevertheless, the fact remains that constructionists attempt to sort out their notions and beliefs using standards of their own convictions and culture.

Peter Cohen (1990), in his discussion of drug use as a social construct, argues that concepts used to describe and explain the phenomenon of drug use are surrounded by bias, a bias produced by a cultural dependency rather than drug use itself. The so-called scientific analysis of drug use, he argues, has often been used as an instrument for survival of the most powerful; power is not only relevant to decision making and resource allocation but also to the social construction of ideology and morality. Scientific constructions and concepts are thus developed according to the interests and tastes of people in power (a trend that is inescapable though may not be justified), and so these constructions often fit into conventional standpoints on topics of research.

The implications of these varying constructionist positions is that, once again, it is not often clear what is, or what should be, socially constructed. Radical constructionism best underscores this basic problem in social construction. Radical constructionists are concerned, for instance, with the domain of technology, with showing how social processes affect the content of technology and what it means for technology to be seen as working. They claim that the meaning of technology, including facts about its workings, are themselves social constructs. Similarly, on the social construction of reality, radical constructionists believe that the process of constructing knowledge regulates itself and that knowledge is a self-organized cognitive process of the human brain, a construct rather than a compilation of empirical data. If this is so, it is impossible to determine the extent to which knowledge reflects an ontological reality.
The problem of social construction has become more pronounced in different constructions of race based on diverging claims on racial distinctions. For instance, while William A. Darity Jr. (2003) has argued that race does not exist because there is no biogenetic basis for racial classifications, studies from Stanford University tend to contradict this claim by suggesting that the way people classify themselves by race reflects real and clear genetic differences among them. They argue that people of different races, even within the same population, have different ancestries, meaning that different genes are inherited from ancestors. However, Hacking (1999) insists that research studies have tended to challenge the idea of race by presenting evidence that the scientific basis for racial distinctions is based on shaky grounds.

Attempts to confine race to social construction appear to be based on the potential dangers of emotions that may be triggered by suggestions that racial differences reflect meaningful biogenetic differences. This has meant that some experts are inclined to publicize the idea that race does not exist. For instance, the New England Journal of Medicine, a prestigious medical journal, editorialized on May 3, 2001, “In medicine there is only one race, the human race.”

But as a social construct, connotations of race change as social, political, historical, and economic structures of society change. Rodney D. Coates (2004) argues that notions of race are created for people to fit into, to raise consciousness in line with conceptual boxes so created, and often to generate racial outcomes, for instance, notions of racial inequality to produce racial superiority. He observes that the construct “black” has in fact changed over time and space, and he questions whether our conceptions of “blacks” have correspondingly changed with the lived experiences and reality of blacks. This invariably reveals the dynamic nature of social reality. If constructions of this lived reality fail to reflect that dynamism, it may become an invalid analytic or discursive unit, that is, a unit or object of analysis or discussion and debate.

Stephen Spencer (2000) has further asked: If race is a social construct, of what is it precisely constructed if not the scientifically invalid false consciousness of biological race? He argues that it is as necessary to problematize the social construction of race as it is to question its scientific construction. He concludes that for those who believe in biological construction of race but not in its social construction, the basis of their construction has an underlying biological conception, whether or not they admit that. Such constructions often create false consciousness, producing uncertainty as to what are or are not social differences and ultimately creating a new consciousness, a new social reality.

These questions highlight the problem of what is and what is not a social construct. The answer may well lie in the fact that it all depends on the researcher’s politics, theoretical orientation, discipline, position in the class structure, or cultural context. It remains that people may often attempt to justify self-serving definitions, but this raises yet another fundamental question: Can this alter consensus on the validity of concepts? It is apt at this point to note that the use of invalid concepts in social research, public discourse, or policy debates may in fact lead to reification. However, in scientific construction, researchers must move outside the boxes of existing notions of matters of investigation to evaluate and analyze issues on such matters from radically different assumptions, even the assumptions of their disciplines (Coates 2004).

SociaL COntract

A social contract is an agreement that can explain and justify a citizen's rights and responsibilities. It can also give an account of our moral obligations and the legitimacy of the state. Social contract theory explores the scope, content, role, and possible justification of any such social contract.

In his dialogue *Crito*, Plato (c. 427–347 BCE) illustrates the power of the notion of a social contract. He depicts Socrates (c. 469–399 BCE) arguing against escaping his prison cell on the eve of his execution. His voluntary residence in Athens and acceptance of the benefits of Athenian society, Socrates claims, show he has implicitly agreed to do the state’s bidding—including accepting its unjust death sentence.

Writers often describe the state of nature as the human condition outside political society. Thomas Hobbes (1588–1679) famously argued that the state of nature is a state of war where life is “solitary, poor, nasty, brutish, and short” (1968, p. 186). Without any settled conceptions of justice, people come to universal and violent conflict. In *Leviathan* (1651) Hobbes describes how individuals secure safety and prosperity only by agreeing with one another to submit themselves completely to an absolute sovereign power. Despite his authoritarian conclusions, Hobbes is one of the founders of the liberal political tradition, which traces political legitimacy and political obligation to the free consent of the governed.

John Locke (1632–1704) denied that the state of nature is necessarily a total war but admitted it has inconveniences (e.g., unfair enforcement of the law of nature). People thus agree to a limited state whose right to rule they may rescind if it is abused. Lockeian liberalism thereby justifies a right of revolution. Not all subjects explicitly agree to a state’s rule, so Locke argued that residence in a state’s territory is implicit consent to the state’s authority. Later commentators, such as David Hume (1711–1776) and, more recently, A. John Simmons (b. 1950), criticized the idea that such tacit consent can make a state legitimate or obligate individuals to obey the laws.

Jean-Jacques Rousseau (1712–1778) believed that both Hobbes and Locke built distorting effects of civilization into their accounts of the state of nature. In Rousseau’s view, civilization introduces all pernicious inequalities (such as in wealth and status), so society should fashion a social contract in order to secure human freedom. The “general will” is properly sovereign; it wills neither private goods nor aggregates of them but wills the common good. Individuals who then voluntarily will the general will best realize their own freedom by sharing in the public good.

More recently, John Rawls (1921–2002) rooted a theory of justice in a social contract whose participants are in an “original position” marked by a fair bargaining situa-

Social Cost

Social cost and social benefit constitute two parts of one phenomenon. They reflect the effect of an economic activity of someone (producer or consumer) on the economic position of someone else who is not directly involved in that activity. Any individual economic decision, and its resulting activity, implies cost in terms of an opportunity foregone, such as opportunity cost. For instance, the labor used for the production of “x” excludes its use for the production of “y.” If the activity causes cost to a third party, this cost must be added to the privately

Andrew I. Cohen
borne opportunity cost. An activity that benefits a third party’s economic position may be defined as a negative cost. The sum of the private cost and the third-party cost is the social cost. The concept of social cost results from economic interdependence.

THE DEVELOPMENT OF INTERDEPENDENCE

British economist Alfred Marshall (1842–1924), in his Principles of Economics, introduced the interdependence phenomenon as “external economies.” Marshall restricted himself to production. For example, external economies concern a localized industry that benefits from the neighborhood of a pool of skilled workers (Marshall [1890] 1920, pp. 266–267). The growth of an industry creates a pool of skilled workers that changes the production technology and its costs. Marshall also gave an external diseconomies example: “English miners have opened out mines of ore which diminished the foreign demand for many of England’s products” (Marshall [1890] 1920, p. 274). English miners and mechanics have aided foreign countries to compete successfully with England’s products. For England its reduced competitiveness will be seen as negative external economies.

In 1931 economist Jacob Viner (1892–1970) launched a distinction in the term interdependence that is relevant to the concept of social cost; technological versus pecuniary external effects. A technological external effect concerns the indirect effect of an activity on consumption bundle, utility function, or production function of someone else. Marshall’s skilled-workers example regards a technological external effect. It implies that privately borne marginal costs differ from social marginal costs. Marginal cost is the extra total cost of an additional unit of production. The disparity between private and social marginal cost results in inefficiency, as the economic decision does not take into account all the relevant costs. Efficiency will be reached if marginal benefits equalize marginal costs, without ignoring the social marginal cost (both positive and negative) on others. The equality concerned is called a Pareto-efficient social-welfare situation. It is a social welfare optimum in which it is impossible to improve someone’s welfare without harming the welfare of someone else. Therefore, disparity between private and social cost offers room for Pareto-efficient changes. Social welfare may profit from changing production or consumption until private marginal costs and social marginal costs are equal to each other, without a loss for anyone. This demonstrates the relevance of the concept of social cost.

A pecuniary external effect concerns an activity of some that has a direct impact on the market prices of others. Person A’s purchase may increase Person B’s input prices. It is similar to a zero-sum game: A’s benefit is B’s loss. Marshall’s miners example is a pecuniary effect. Pecuniary external effects concern redistribution of rent, irrelevant to the concept of social cost. However, in an international context this redistribution may result nationally in welfare effects and social cost.

EXTERNAL EFFECTS THAT RELATE TO SOCIAL COST

In the 1920s British economist Arthur C. Pigou (1877–1959) formulated a remedy to welfare inefficiencies due to inequalities between private and social marginal cost. If private marginal cost exceeds social marginal cost, there is a positive external effect. A subsidy that equalizes private and social cost enables governments to prompt social welfare. For instance, the privately borne cost of education may exceed its social cost due to the social benefits of education, i.e., negative social costs. A subsidy to the education consumer will prompt education, equalizing private to social cost, enhancing Pareto-efficiency. The subsidy will induce additional activity that promotes social good. In the reverse case, there is a negative external effect that ought to induce governments to levy a tax on the activity that causes a negative effect on society.

The Pigovian procedure is beset by a multitude of difficulties. First, the discrepancy between private and social cost depends on the scope of the external effect. Should future generations be taken into account as being part of the harmed or favored third party? Second, cost differs substantially over time. In the short run it is hard to adapt to an effect. Therefore, in the long run the cost issue of an external effect will weaken. Third, costs and benefits pertain to individuals who may value these in a subjective manner. This subjectivity blocks an objective aggregation.

Even a compensation test in which winners compensate losers is not possible without a normative element. After compensation, winners as well as losers might reverse their valuation. While applying the compensation test, a normative assumption about the distribution desired must be made. All these implementation difficulties turn the Pigovian welfare device in what, later on, economist Ronald H. Coase (b. 1910) typifies as “blackboard economics” (Coase 1988, p. 19). Pigou does not take the informational problems into account that surround his proposal. In particular, the tax-subsidy instrument becomes arduous because of diffuse external effects.

Nevertheless, the Pigovian approach is a popular line of thought in designing public policy. In particular cost-benefit analysis endeavors to cope with the measurement and aggregation problems discussed, making explicit the integral (net) sum of private and social cost. Such an analysis may, for instance, imply an appraisal of the negative social cost of safety investments in terms of the cost of a human life.
THE PROBLEMS OF SOCIAL COST

In 1960 Coase wrote The Problem of Social Cost, a paper that addressed the basic cause of the discrepancies between private and social cost. Why do markets fail to bring parties together that might be mutually profitable? For instance, Person A's activity inflicts a harm on Person B. It is in line with the Pigovian approach to tax Person A, to prohibit A's activity, or to make A liable for the harm inflicted on Person B. However, according to Coase, this "traditional approach has tended to obscure the nature of the choice that has to be made" (Coase 1960, p. 2).

The choice in the social-cost issue is a reciprocal choice. For example, to prohibit Person A's activity will certainly favor Person B, but, simultaneously, it will harm A. If A's activity brings in a benefit of $50, and if this activity harms B for $20, banning A's activity is socially inefficient. This perspective opens new insights. Person A's activity and Person B's harm should be formulated in terms of property rights. Consequently, A and B will start negotiations about their conflicting rights. A market emerges, and the social-cost concept turns out to be irrelevant. A precondition is that the transaction cost is zero. This is the Coase Theorem in a nutshell.

His theorem aims to underline that in reality, transaction cost is positive. In particular, transaction cost will be substantial if great numbers of parties are involved in an external effect. These abound in modern industrialized economies (e.g., air pollution due to production and consumption). The Coasean program aims to design social arrangements that internalize social cost and minimize transaction cost. Internalized social cost will be borne by optimizing economic agents and, consequently, minimized. The Kyoto Protocol in 1997, which established CO₂-emission rights among nations, is such a social arrangement. Trade on emission rights has emerged, which reduces social cost.

SOCIAL DOMINANCE ORIENTATION

Social dominance theory proposes that humans have an evolved tendency to form group-based social hierarchies because such social structures were adaptive in evolutionary history. Influenced by Marxism, the theory observes that group-based hierarchies are cross-culturally universal and are stratified according to criteria: age, gender, and arbitrary-set group memberships, including socially constructed categories such as ethnicity and social class. Social dominance theory describes how sociostructural, psychological, institutional, and ideological factors interact to produce and maintain hierarchically organized social structures that foster discrimination and oppression within society.

Social dominance orientation is the psychological component of social dominance theory. According to Jim Sidanius and Felicia Pratto (1999), social dominance orientation reflects the degree to which people are predisposed to achieve and maintain hierarchically organized social structures in which some groups dominate and have more power than others, versus social structures in which all groups are equal and no one group has more power than any other. This global orientation encompasses the competitive-driven motivation to achieve and maintain group-based dominance and unequal power relations between any given set of social groups, regardless of the particular categories or characteristics used to define those groups (e.g., gender, ethnicity, social class). Social dominance orientation is measured by assessing the extent to which people agree with ideological/attitudinal items such as “Some groups of people are simply inferior to other groups” and disagree with items such as “No one group should dominate in society.”

Social dominance theory states that the motivation for group-based dominance and superiority (indexed by
social dominance orientation) is a proximal cause underlying the many different manifestations of prejudice and discrimination (e.g., sexism, racism, homosexual prejudice), and also explains why some people are more likely to seek out positions of power and status. Consistent with this perspective, research demonstrates that people who are prejudiced toward one group will also tend to be prejudiced toward other (often unrelated) groups, and that the generality of prejudice toward multiple groups is reliably predicted by individual differences in social dominance orientation. These effects occur because, regardless of qualitative differences in content, prejudice and related ideologies (such as meritocracy and cultural elitism) function as legitimizing myths that produce and maintain hierarchically organized social structures. Accordingly, group-based hierarchies should tend toward stability to the extent that such ideologies are consensually shared across both dominant and subordinate groups within society (a phenomenon referred to as behavioral asymmetry).

Social dominance orientation explains an aspect of prejudice that is not accounted for by other constructs, such as right-wing authoritarianism or political conservatism. Individual differences in social dominance orientation are caused by a combination (and possible interaction) of biological factors (men are typically higher in social dominance orientation than women), sociostructural factors (group membership and exposure to competitive social environments), personality or temperament, and schematic beliefs about the competitive (versus cooperative) nature of the social world. Although there is some debate regarding the extent to which social identity might contextually activate social dominance orientation, most researchers nevertheless agree that the orientation functions as a mechanism through which the aforementioned factors produce individual differences in prejudice and hence institutionalized discrimination and oppression.

**SOCIAL ECONOMY**

The social economy is generally taken to be a third sector of mixed capitalist economies distinct from the private and public sectors. The social economy is based on cooperative, not-for-profit, and voluntary rather than paid activities carried out within communities, across national economies, and internationally. It is variously referred to as the nonprofit sector, the *économie sociale*, and the *Gemeinwirtschaft*, and has a long history coincident with the rise of market economies (Nitsch 1990).

The social economy is defined by the collection of different social objectives of the various organizations that make it up. According to the European Commission, social economy organizations are classified as cooperatives, mutual societies, voluntary organizations, foundations, and social enterprises. All are based on voluntary participation and membership, and are guided by their social objectives rather than a need to make a return on capital. Many social economy organizations simply deliver services to their members or others they aim to serve without making use of the market. Other social economy organizations, known as social enterprises, engage in trade activities in order to benefit their members or those they serve. In this latter case, any surpluses or profits earned are reinvested in the enterprise, distributed to stakeholder groups, or used for the benefit of those served by the enterprise. Governance typically operates through the “one member, one vote” principle or through enterprise trustees.

A diverse range of examples of social economy organizations includes building and mortgage societies, credit unions, charities and philanthropic organizations, neighborhood organizations and community groups, trade unions, insurance mutuals, sports associations, hospitals, self-help groups, school organizations, religious groups, environmental groups, arts groups, clubs of many kinds, political organizations, producer cooperatives, trade and professional associations, and job-training organizations.

Recognition of the economic importance of social economy enterprises—treated as nonprofits in the economics literature—is relatively recent (e.g., Rose-Ackerman 1986; Weisbrod 1988; Ben-Ner and Gui 1993). But social economy enterprises, or nonprofits, are now seen to play significant economic roles in addressing needs unmet by the private and public sectors, competing with for-profit enterprises, enhancing economic productivity, improving delivery of public services, promoting economic and social development, and providing employment. In addition, because worldwide trends are toward both increasing services production and privatization of government services, social economy or nonprofit enterprises, many of which address these domains, are likely to play larger economic roles in the future. This is reflected in more explicit recognition of the social economy in the...
national economic policies of many countries, including the United Kingdom, Spain, France, Canada, and a num-
ber of Latin American countries.

SOCIAL EXCHANGE THEORY

While the general study of market exchange is the domain of the discipline of economics, the social, interactional components of exchange (in a market context or not) interest other social scientists. As German sociologist Georg Simmel noted: “Exchange is not merely the addition of the two processes of giving and receiving. It is, rather, something new. Exchange constitutes a third process, something that emerges when each of these two processes is simultaneously the cause and the effect of the other” ([1907] 1971, p. 57).

Noneconomic investigations of exchange appeared in anthropology in the 1920s. For example, in 1922, Bronislaw Malinowski published a study of islander life that analyzed status components of exchanges that were different from (although related to) simple consumption or material interests. Other anthropological studies followed that emphasized the importance of gift giving and reciprocity for the maintenance of cohesive relationships.

A series of sociological and psychological studies of exchange emerged in the 1950s. George Homans adapted behavioral or operant learning tenets to describe behavior among individuals. Because operant principles emphasize how individuals act on the basis of previous experience, Homans’s formulation also focused on the past as predictive of future behavior. He presented human exchanges as involving rewards and costs and argued that people responded to these exchanges so that benefits outweighed costs. Somewhat different from Homans’s approach, Peter Blau developed a more economic framework in his exchange formulations. So, for example, in his analysis of bureaucracies, he pointed out that people compete for scarce resources and trade different social commodities (such as advice).

In psychology, John Thibaut and Harold Kelley developed their theories of social power that involved the idea that the amount of power one individual or group possesses is determined, in part, by the alternatives present. Thus, individuals gauged whether to engage in exchanges dependent upon the value of the exchange itself and if alternatives were available. Alternatives also affected the way comparisons among activities were perceived; that is, what was experienced in the past affected how attractive or unattractive a particular option appeared.

Richard Emerson’s formulation of power-dependence theory in social relations took these previous conceptualizations and developed an overarching theory. It specified a relational aspect to power that placed the exchange relation as central. Power was inversely related to dependence: For a given exchange relation, the more powerful an individual or group, the less dependent on the relation. Further, Emerson’s theory posited a continual balancing mechanism in exchange relations. If people had power, they used it because it gave them advantage. But, if power was used, it was (incrementally) lost. This shift of power leads to balancing.

Further distinctions in different kinds of exchanges emerged in work that followed. Specifically, Linda Molm distinguished two types of exchanges that had different properties. Negotiated exchange involves bargaining and negotiation and then agreement upon the terms of the exchange. In contrast, reciprocal exchange does not involve negotiation but, instead, is comprised of individual acts performed for an other or others without knowledge about future reciprocation. Given equivalent costs and benefits, reciprocal exchanges generate more trust and affect than do negotiated exchanges. Part of the reason for this is that, at least under some conditions, risk generates trust.

Molm investigated coercive power in these nonegriated exchanges as well. Coercive power (in the sense of punishing others) is seen by participants as intentional and most likely to be used when an actor has little reward power. This is probably the case because coercion is risky and can decrease the possibilities of future beneficial exchanges. So, even though punishment can be an effective strategy if it is consistently and contingently applied, actors do so relatively infrequently.
While there are differences between negotiated and reciprocal exchanges, there are similarities as well. One important similarity rests with the negative emotion that can be generated with power use. For example, the conflict spiral, a theory about bargaining processes, documents that unequal power, even without punishment, can produce negative emotion.

Much of the research on negotiated exchange has focused upon the idea of alternatives to valued resources and so has considered exchange networks. Relative power of positions in simple networks can be analyzed by calculating the alternatives to a given position. Depending upon the number and extent of alternatives within the network, different kinds of relationships can be defined. Particularly important for the exercise of power is the ability to exclude others. The network then can define strong, equal, or weak power. There have been a number of attempts to find methods of predicting power in networks that vary in structure and size. There is the graph theoretic approach, a game theory approach, and an expected value mode, among others.

Emotion is also implicated in the exchange process. The affect theory of social exchange, for example (see, in particular, Lawler 2001), maintains that while social exchange has an instrumental and individual function, the exchange itself involves a group product that fosters emotional, affective processes. While rational choice formulations had examined how commitment in exchange networks was fostered by uncertainty reduction, it has been demonstrated that affect, in and of itself, can also generate commitment. Productive exchanges provide particularly strong arenas for emotion. These exchanges occur in settings in which group members have equal power, coordination issues exist and must be solved, and interdependence of group members is necessary for production of the outcome.

While the study of exchange has always been important to group dynamics, the addition of emotion and notions of risk, trust, and uncertainty has transformed early investigations of simple cost and benefit. The transformations have expanded both the depth and scope of exchange formulations. For example, depth has been transformed by analysis of actors’ strategies in the face of contingencies, and scope has been transformed by analysis of the network configurations under which exchange occurs. In this regard, different disciplines have contributed different insights to the study of social exchange: game theory in economics has focused upon strategies, anthropology has emphasized the cultural components implied in cohesive groups, psychology has investigated issues related to risk and uncertainty, and sociology has focused upon the network structure under which exchange occurs.

Social Exclusion

Social exclusion is less a single issue capable of empirical exploration than a way of viewing, or an orientation toward, society. The term itself implies on the one hand groups of people who are in some sense marginalized from society and on the other a societal mainstream composed of people who are not excluded. The range of excluded groups is very wide, extending from those subject to racism to older people, from those who are unemployed to those subject to homophobia, from those who are disabled to disillusioned youth, from the mentally ill to teenage mothers (Sheppard 2006).

There are, perhaps inevitably, an equally large number of definitions, although most contain the common “mainstream-marginalization” theme. The definition that perhaps best expresses the meaning of social exclusion was provided by the Child Poverty Action Group: Social exclusion "refers to the dynamic process of being shut out,
fully or partially from any of the social, economic, political and cultural systems which determine the social integration of the person in society” (Walker and Walker 1997). This definition gives the sense of being “outsiders,” unable to participate fully in society, and that the problem was systemic, in that it involved—whatever the cause—social systems.

THE CONCEPT
Discussions of social exclusion reflect the effects of the great range of groups to which the term is applied. As a response to the conceptual difficulty of embracing such a range, one approach is to focus on a particular group, providing a “practical marker” for social exclusion. Unemployment, in particular, has provided such a focus, as it is regarded by many as the key issue liable to be associated with social exclusion, and also to be part of the situation confronted by many excluded groups such as the racially disadvantaged, disillusioned groups, and poor families.

The primary factor in social exclusion, from this perspective, is unemployment. At an individual level it has a profoundly demoralizing effect when sustained, and at societal level, it provides a threat to social cohesion and stability. The experience in pre–World War II Europe of the political effects of unemployment, and its association with the rise of fascism, provides a background in recent history of the societal threat presented to social order, both within and between [nation-] states. Late-twentieth-century structural changes in the European economies, which saw higher rates of long-term unemployment, fueled a concern for social inclusion policies (Commission for the European Community 1992).

In Britain, France, Germany, and the Netherlands, social exclusion policies have emphasized unemployment and reemployment. By this logic, policies promoting social inclusion should first and foremost be focused on reintegrating the unemployed into the workforce and enabling this to occur through appropriate economic and social measures. In doing so, such policies would be expected to have a secondary effect on other features of social exclusion. Unemployment often has been used as a practical “shorthand” for poverty, underlying a range of issues of social concern relating to poor workforce skills, low income, poor housing, high crime environments, bad health, and family breakdown (Atkinson and da Voudi 2000, p. 435).

A more abstract, and hence more embracing, notion has connected social exclusion and inclusion to the “realization of human potential.” Individuals and groups suffer social exclusion to the extent that society does not offer them the opportunity to realize their potential. This notion of rights—that people have a right to achieve their potential, in conjunction with their fellow citizens—is embedded in the very heart of the European Union (EU). It takes precedence over, and makes sense of, some of the union’s most fundamental aims: “economic and social progress,” states the Comité des Sages, an official group of prominent experts from the EU whose task is to inform policy development, “must be subordinate to this aim” (1996, p. 26). It also links social exclusion with equality of opportunity. In Britain this was formulated by Chancellor Gordon Brown, who argued that everyone deserves to be given an equal chance to fulfill “the potential with which they are born” (1997). Poverty and unemployment could provide obstacles to this, but so could other disadvantages, which are multidimensional, such as health, disability, and age.

A range of responses could be made to these obstacles to inclusion and full social participation in the spheres of education, welfare, and the economic sector. For example, good educational provision, universally provided, provides a strong basis of opportunity for individuals to achieve their potential. All these strategies help promote an idea of “citizenship,” which is closely associated with the realization of potential. Citizenship involves participation and involvement in society, and hence the realization of human potential becomes, in part, an active concept focused on social participation.

Education can actively enhance the capacity for citizenship. However, other provisions, for example, the range of welfare support, can counteract or ameliorate the effects of disadvantage that prevent individuals or groups from being citizens. Citizenship stands as a means for curbing the excesses of the market, particularly through the welfare state (Marshall 1963). Material issues of economic inequality are important in this respect, but so too are prejudice and stigma suffered by some groups, affecting their life opportunities, sense of identity, and self-esteem.

Social citizenship involves living “the life of a civilised being according to the standards prevailing in society” (Marshall 1963, p. 74; Kymlicka and Norman 1995). What it is asked, do people need in order to participate in society fully as citizens? One approach is that of “passive recipient,” in which professionals, as experts, identify and design responses to need. The doctor, counselor, or social worker is entrusted with ensuring that an individual’s needs are met. An alternative—with more active involvement—emphasizes the capacity of citizens to define, and act upon, their own needs. This rebalances the relationship between service provider and recipient. The service user becomes the “expert” in assessing his or her own needs, and the service provider becomes the facilitator of the response to that need (Smale et al. 1993). This covers the individual level, but it can apply also to groups
or communities. In such a scenario, local communities come together in groups actively to improve their own lives, involving, say, community action in relation to rundown neighborhoods or local crime. When a group is active, they are taking up and enacting their rights as citizens. This notion of citizenship involves “realization of potential” in two respects. First, it becomes an aim of their actions, and second, it is embedded in the processes by which they seek to achieve these aims. As active citizens they are enacting their potential.

**SOCIAL EXCLUSION AND THE PROBLEM OF ORDER**

Human potential may underlie one aspect of social exclusion. Another aspect is the problem of order. One (politically liberal-left) approach relates social exclusion and social order to the notion of the “just society.” Walter Runciman suggested that peoples’ sense of justice, and hence their sense of grievance, arose in the context of reference groups (1972). They measure their own situation, and rewards, by reference to others whom they consider to be like them. For example, plumbers might compare themselves with electricians, and expect similar rewards, but be unworried by being rewarded less than doctors.

A sense of justice and fairness, and therefore of inclusion and exclusion, involves those to whom people make reference. They do so in two ways. First, there are groups within society with whom people compare themselves, and second, on a wider basis, the general wealth of their own society, and its distribution, provides a reference. No one expects standards appropriate to nineteenth-century European societies to provide a reference for those same societies in the twenty-first century.

Runciman argued that three principles could justify distribution of wealth and status: those of need, merit, and contribution to the common good. However, there should be a limit to the degree of inequality. Following John Rawls (1971), he argued that the test of inequality was whether it could be justified to the losers, and for the winners to do this, they must be prepared, in principle, to change places (Runciman 1972, p. 307). It is also a test for a sense of inclusion, because acceptance would indicate commitment to a set of common fundamental norms and expectations widely accepted in society.

A just distribution of resources, then, is necessary to avoid a sense of social exclusion liable to feed political instability. The danger presented by poverty relative to others is that it could lead to a feeling of exclusion “from normal living patterns” (Townsend 1979, p. 32) and hence of alienation from participation in social life. Poverty, therefore, is not just material but emotional. The promotion of social inclusion should be at societal level, including incomes policy, full employment, higher social security, and a more redistributivist tax structure.

A (liberal-right) alternative to this societal distribution approach is one that emphasizes personal responsibility. A range of writers (Murray 1994; Field 1996; Etzioni 1995, 1998) have expressed concern about the development of a “moral underclass” not committed to the values of mainstream society, which might have a corrupting impact on mainstream society. According to these writers, welfare dependency, high crime rates, single parenthood, teenage pregnancies, and a decline in traditional family values characterize this underclass.

Amitai Etzioni considered parenting deficits to be the underlying feature in the development of a moral underclass (1998): When parents do not commit themselves enough to their children, a moral deficit amongst the young emerges. Children from single-parent and broken (particularly divorced) families are particularly vulnerable. Etzioni emphasized the need for moral renewal based on socialization, which would create shared norms helping bind society together. The key agencies of this [re]socialization are education and child welfare. Policies supporting parents—including welfare-to-work and penalties for parents whose children are school nonattendees—also would encourage them to engage better with their moral responsibilities.

Charles Murray considered a large proportion of welfare-dependent families were in circumstances of their own making (1994). According to Murray, on the one hand, this group increasingly makes the wrong moral choices, including sustained unemployment, crime, and illegitimate childbirth; on the other, welfare policies, specifically social security benefits, create perverse incentives for them to remain welfare-dependent. For example, teenage pregnancy (and motherhood) is encouraged by the state’s giving the impression that once a child is born, housing and other financial benefits will be made available. Social policy needs to be directed not just at resocialization at the personal level, but also in policies (such as low benefits) that are a disincentive to welfare dependency.

Although undoubtedly influential on government policy making (Prideaux 2005), Murray’s concept of the underclass has been heavily criticized. The concept, it is argued, diverts attention from wider social, economic, and political causes of poverty (Williams and Pilinger 1996). A commonly accepted assumption about the underclass is that poverty is “intergenerationally transmitted” (i.e., that it passes down from generation to generation), but Murray has emphasized culture, and more recently genetics, as key factors (Fitzpatrick 2001). However, evidence indicates that the benefits bestowed by wealth (or disadvantages associated with its absence) and “networks of association”
(who you know) also are important features (Bartholomae et al. 2004). Where these facets are not recognized, the danger arises of "blaming the victim"—that is, erroneously presenting the victim's poverty, disadvantage, and welfare dependence as being his own fault (Ryan 1976).

Teenage pregnancy, an example of an issue of wide concern in developed countries, shows the impact of these two (liberal-left and liberal-right) orientations. It is associated with other social concerns—poverty, unemployment, criminality, and so on—and has a negative impact on life chances. Countries with social policies that reduce inequalities, including Norway, Sweden, and Holland, have the lowest rates of teenage pregnancies, whereas more unequal countries, such as the United Kingdom and United States, have much higher rates. Nevertheless, even countries that have been only moderately successful at reducing teen pregnancies have included education and contraception as policy responses, underlain by normative, personal responsibility features (UNICEF Innocenti Research Center 2001).

**THE FUNCTIONALISM OF SOCIAL EXCLUSION**

Underlying all these approaches is a consensus functionalism that would be recognizable to Talcott Parsons (1951) and Émile Durkheim (1947). This is reflected in an emphasis on the widespread adoption of common norms that would create order and stability in society, which would also be in the interests of individuals and groups. The means by which this would be achieved vary, depending on the ideological commitment of the protagonists.

Criticisms of social exclusion as an approach arise because of the ideological nature of the very term. Its use, some think, does a disservice to the vast range of phenomena with which it deals, drawing attention away from the specific issues attached to each of them. Furthermore, it assumes that those who are socially excluded should aspire to the values of mainstream society: This may not be what they want, and they may see no reason to do so. Lastly, it has an implicit notion of the "good society" encapsulated in these mainstream values. This notion may itself be contested.

SOCIAL EXPERIMENT

A social experiment is the random assignment of human subjects to two groups to examine the effects of social policies. One group, called the “treatment group,” is offered or required to participate in a new program, while a second group, the “control group,” receives the existing program. The two groups are monitored over time to measure differences in their behavior. For example, a social experiment can compare a program that gives unemployed individuals a financial reward for finding a job with one that does not. Or, a social experiment might compare students in schools that receive a new curriculum with students in schools that do not. Because the randomization procedure guarantees that the two groups are otherwise similar, the measured differences in their behavior can be causally attributed to the new program. The behavioral differences are sometimes called the “impacts” of the program. Commonly measured behavioral outcomes in social experiments include earnings, employment, receipt of transfer payments, health, educational attainment, and child development. Sample sizes in social experiments have ranged from under 100 to well over 10,000.

Some social experiments have more than one treatment group. In such cases, each treatment group is assigned to a different program. The various treatment groups may be compared to each other to determine the differential impacts of two of the tested programs, or they may be compared to the control group to determine the impact of the program relative to the status quo. The human subjects may be chosen randomly from the general population or, more commonly, may be chosen randomly from a target population, such as the disadvantaged.

Social experiments have been used extensively since the late 1960s. According to Greenberg and Shroder (2005) almost 300 social experiments have been conducted since then. Social experiments are very much like medical laboratory experiments in which the treatment group is given a new drug or procedure, while the control group is given a placebo or the standard treatment. Laboratory experiments have also been used extensively in the field of economics, since the 1970s (Smith 1994), but they differ from social experiments in that they are used mainly to test various aspects of economic theory, such as the existence of equilibrium or the efficiency of market transactions, rather than the effects of a social program. Also, economics laboratory experiments usually do not have a control group; instead, cash-motivated members of a treatment group are given the opportunity to engage in market transactions in a controlled environmental setting to determine whether they behave in a manner consistent with the predictions of economic theory. Some laboratory experiments in economics have been used to test public policy alternatives.

HISTORY OF SOCIAL EXPERIMENTS

Much of the foundation of the modern approach to social experimentation can be traced back to the work of the famous statistician Ronald Fisher in the 1920s. Fisher refined the notion of random assignment and pointed out that no two groups could ever be identical. He noted that allocation of subjects to treatment and control groups by pure chance (by the flip of a coin or from a table of random numbers, for example) ensures that differences in the average behavior of the two groups can be safely attributed to the treatment. As a result, the direction of causality can be determined using basic statistical calculations. Fisher also recognized that randomization provides a means of determining the statistical properties of differences in outcomes between the groups.

The first major social experiment was the New Jersey Income Maintenance Experiment, which was initiated in the United States in 1968. Although a few smaller social experiments preceded the New Jersey Experiment (such as the Perry Preschool Project in 1962), they were much smaller in scope and much less sophisticated. The New Jersey Experiment tested the idea of a negative income tax (NIT), first proposed by the economists Milton Friedman and James Tobin in the 1960s. The New Jersey Experiment was the first of five NIT experiments conducted in North America (four in the United States and one in Canada) that had very sophisticated designs and many treatment groups. Problems evaluating certain aspects of these complex experiments led to much simpler experimental designs in ensuing years.

From the 1970s to the present, social experiments have been conducted in numerous social policy areas, including child health and nutrition, crime and juvenile delinquency, early child development, education, electricity pricing, health services, housing assistance, job training, and welfare-to-work programs. Notable experiments include the Rand Health Insurance Experiment, which tested different health insurance copayment plans; the Moving to Opportunity Experiments, which tested programs enabling poor families to move out of public housing; four unemployment insurance experiments that tested the effects of various financial incentives to induce unemployed individuals to return to work; and a number of welfare-to-work experiments that tested ways of helping welfare recipients find jobs.

LIMITATIONS OF SOCIAL EXPERIMENTS

Although widely acknowledged as the ideal way to determine the causal effects of proposed social policies, social experiments have several important limitations. First, and perhaps most importantly, social experiments require that a control group be denied the policy change given to the
treatment group. Because control groups in social experiments are typically disadvantaged, denial of program services may be viewed as constituting an ethical breach, thus limiting social experiments to places where resources prevent all eligible individuals from being served. Also, treatments that make a participant worse off are also viewed as unethical and politically infeasible.

Second, although well-designed experiments have a high degree of internal validity (inferences are valid for the tested sample), they may not have external validity (they are not generalizable to other settings). One common criticism of experiments is that because of their limited size, they do not generate the macroeconomic, “community,” effects that a fully operational program would generate. For example, a fully operational job training program may affect the wages and employment of nonparticipants and may affect social norms and attitudes, whereas a limited size experiment would not. Additionally, there is no way of knowing for sure whether a successful experiment in one location would be successful in another location, especially because social experiments are typically conducted in places that are chosen not randomly, but for their capability and willingness to participate in an experiment.

Third, social experiments take time to design and evaluate, usually several years. Policymakers may not want to wait the required time to find out if a particular program works.

Finally, in practice, it has often proven difficult to implement random assignment. For one reason or another, individuals may not be willing to participate in a research study, and in cases where collaboration between researchers and government agencies is required, some may be unwilling to participate. As a result, the treatment and control groups that are tested may turn out to be unrepresentative of the target population.

Because of the various limitations of social experiments, other means of evaluating the effects of social policies have been developed. These are generally termed “nonexperimental” or “quasi-experimental” methods. Nonexperimental methods monitor the behavior of persons subjected to a new policy (the treatment group) and select a “comparison group” to serve the role of a control group. But because randomization is not used to select the two groups, it is never known for sure whether the comparison group is identical to the treatment group in ways other than receipt of the treatment. Many researchers match treatment group members to persons in the nonparticipating population to make the groups as similar as possible. The matches are usually done using demographic and economic characteristics such as age, education, race, place of residence, employment and earnings history, and so on. One popular matching technique is propensity score matching, which uses a weighted average of the observed economic and demographic characteristics of the nonparticipating population to create a comparison group.

A particularly attractive nonexperimental method is the “natural experiment.” Natural experiments often are used to test the effects of social policies already in place. The natural experiment takes advantage of the way a new policy has been implemented so that the comparison group is almost a true control group. For example, military conscription (being draft eligible) during the Vietnam War was done by a national lottery that selected individuals for military service solely according to their date of birth. Thus, theoretically the group selected for military service should be identical to those not chosen, because the only difference is date of birth. Researchers wanting to test the effects of military conscription on individuals’ future behavior could compare outcomes (for example, educational attainment or earnings) of those conscripted with those not conscripted and safely attribute the “impacts” to conscription (Angrist 1990). Because not all conscripted individuals actually serve in the military and because some non-conscripted individuals volunteer for military service, it is also possible to estimate the impact of actual military service on future behavior by adjusting the impacts of conscription for differences in the proportion serving in the military in the treatment and comparison groups. However, the validity of this procedure rests crucially on the comparability of the military service veterans in the two samples.

THE FUTURE OF SOCIAL EXPERIMENTS

Social experiments have changed in character since the late 1960s. Many early social experiments such as the NIT experiments, the Unemployment Insurance Experiments, and the Rand Health Insurance Experiment tested a “response surface” in which subjects were given “quantifiable” treatments of varying tax or subsidy rates. In contrast, most of the more recent social experiments are “black box,” meaning that a package of treatments is given to the treatment group, and it is not possible to separately identify the causal effects of each component of the package.

Black-box experiments have been criticized because they tend to have much less generalizability than response-surface experiments. Hence, many researchers have called for a return to nonexperimental evaluation as the preferred method of analyzing the effects of social policies. However, those favoring experimental methods have countered that social experimentation should remain the bedrock of social policy evaluation because the advantages are still great relative to nonexperimental methods (Burtless 1995). In an attempt to “get inside the black box,” those sympathetic with the social experiment as an evaluation tool have proposed ways of combining experi-
mental and nonexperimental evaluation methods to identify causal effects of social policies (Bloom 2005). Nonexperimental methods are necessary because of a selection bias that arises when members of the treatment group who receive certain components of the treatment are not a random subset of the entire treatment group. In the future, social policy evaluation may make greater use of both evaluation methodologies—using experiments when feasible and combining them with nonexperimental methods when experiments cannot answer all the relevant policy questions.

SOCIAL FACILITATION

In 1898 Norman Triplet reported an experiment in which schoolchildren turned a fishing reel under two conditions: first alone and then standing beside a competitor. Triplet claimed that the competitor’s presence inspired many of his subjects to perform the reel-turning task more quickly. In his 1924 textbook Social Psychology, Floyd Allport offered a behavioral interpretation of Triplet’s result. As Allport explained, responses elicited by a nonsocial stimulus can be augmented by a social stimulus. Allport regarded Triplet’s finding as evidence of this social facilitation and offered some evidence of his own. In Allport’s research, college students solved simple multiplication problems and cancelled vowels from English text more quickly when working alongside other students than when alone.

In contemporary usage, the term social facilitation has a broader meaning, referring to any influence of the presence of others on the individual. The others who are present may be doing the same thing as the individual (that is, coacting), or they may simply be observing. Most often, researchers study influences on the individual’s performance of a task. Sometimes they find that individuals perform tasks better in the presence of others than when alone, but often they find the opposite: worse task performance when others are present. Both performance improvements and performance degradations are termed social facilitation, as the phrase is currently used.

When does the presence of others benefit task performance and when does it impair task performance? Robert Zajonc offered an answer to this question in 1965. According to Zajonc, the presence of others improves the performance of simple tasks and disrupts the performance of complex tasks. Although subsequent research provided some support for Zajonc’s assertion, a large-scale review showed in 1983 that the presence of others impairs complex performances more strongly than it facilitates simple performances (Bond and Titus 1983).

What accounts for these effects? Zajonc proposed an answer to this question too. Zajonc wrote that the presence of others functions as a source of generalized drive, enhancing dominant response tendencies. According to this analysis, the dominant tendency is to give the correct response on simple tasks and to make mistakes on complex tasks. By enhancing these tendencies, the presence of others facilitates simple task performance and impairs complex performance, Zajonc’s drive theory claims.

Other theories of social facilitation have been proposed. These note that the presence of others can induce many psychological states, including self-awareness, distraction, and evaluation apprehension. Psychophysiological theories have been proposed. Whereas an older theory claimed that the presence of others increases general arousal (Guerin 1993), Jim Blascovich and colleagues offered a different view in 1999: When others are present, people who are performing simple tasks manifest physiology indicative of challenge; those who are attempting complex tasks manifest physiology indicative of threat.

The presence of others influences more than task performance. It can encourage the display of prejudice. It can increase, and sometimes decrease, how much people eat. It has many effects on animal behavior. A rudimentary form of social influence, social facilitation has captured psychologists’ attention for more than a century.

Social Identification

In this way, the individual develops identity by interacting with others, through presenting desirable impressions according to the social expectations in a particular socio-cultural context.

In *The Reproduction of Mothering* (1999) Nancy Chodorow provides a psychological analysis of the construction of gender identity in the intimate social surroundings of family. According to Chodorow, gender identity is the consequence of a specific family form in which women are exclusively responsible for the nurturing of children. Children build their gender identity by differentiating themselves from their primary caregivers, usually their mothers. Because the early social environment differs and is experienced differently by male and female children, Chodorow argues that individuals develop different gender identities based on sex. Her research has been particularly influential in explaining how patriarchal practices of Western cultures affect individual identification processes.
